Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

SUPPLEMENT TO "THE ELECTRICAL ENGINEER," JUNE 28, 1895.

THE

ELECTRICAL ENGINEER.

A WEEKLY JOURNAL OF ELECTRICAL ENGINEERING,

WITH WHICH IS INCORPORATED

"ELECTRIC LIGHT."

VOL. XV. (NEW SERIES.)

FROM JANUARY 4, 1895, TO JUNE 28, 1895.

LONDON:

Printed and Published for the Proprietor by BIGGS & Co., at "THE ELECTRICAL ENGINEER" Offices, 139-140, Salisbury-court, Fleet-street, E.C.

1895.

Digitized by Google

INDEX TO VOL. XV. (New Series.)

NOTE.—General Articles, Correspondence, and Companies' Meetings are indicated by heavier type (thus, 290) than the Notes and Business Notes, references to which are shown by light type (thus, 290).

A.

Aberdeen Corporation Electricity Works, Accounts of, **456**
Absolute Measurement of Electrical Resistance, Prof. J. V. Jones, **688**, 709
Accumulator, An Extraordinary, **402**
Accumulator, A New Lead, 324
Accumulators, Chloride, 8. 89, 119
Accumulators, Powdered Lead, **248**, 273
Accumulators, Use of, J. C. Howell, **591**. **683**
Advertising by Electricity, 30, 466
Agencies. 205, 237, 270, 296, 410, 669, 751
Albert Medal, 301
Alkaline Deposits on Electric Light Mains, **451**
A Little Knowledge is a Dangerous Thing (*London's* Opinion on Consulting Electrical Engineers), 551
Alternating-Current Lines, Resonance in, 561
Alternating-Current Motors, A. Rothert, 524
Alternating-Current Motors, Practical Application of, W. J. Fryer, **250**, **278**
Alternating and Interrupted Electric Currents, Prof. Forbes, **476**, **502**, **540**. **572**. **601**, **632**
Alternator, General Electric Company's 800-Kilowatt, 4
Ambroin, New Insulating Material, 701
American Electro-Therapeutics, 677
American Institute of Electrical Engineers, 493, 673
American Patent System, 62, 273, **349**
Amoretti, P., Steam Tramways in Italy, **279**
Amsterdam Exhibition, Electricity at, 614
Anachronism, An (Electric Lighting in "Harold"), 673
Antiquity of the Incandescent Lamp (Whale in "Jonah," Jewish Play), 584
Anti-Smoke (Leading Article), **102**
Application of the Electric Arc System of Welding to Machinery and Boiler Repairs, H. Foster, **196**, **218**
Appointments, 29, 84, 101, 112, 145, 176, 177, 196, 273, 275, **296**, **322**, **353**, 410, **433**, 577, 732
Appointments Vacant, 30, 58, **85**, 145, 237, 238, 270, 271, 354, 382, 433, 462, 578, 641, 669, 695, 752
Apprentices' Institution, The, 732
Arc Carbons and the Rating of Arc Lamps, L. B. Marks, **341**
Arc Dynamos, Large, C. N. Black, **402**
Arc Lamp, New Alternating-Current, **307**
Arc Lamps, Economical Working of, 181
Arc Lamps, Rating of, and Arc Carbons, L. B. Marks, **341**
Arc Light Carbons, B. F. Miles, **107**, **156**
Arc Lighting, Coupling of Dynamos for, W. H. Lea, **399**
Are Horses Doomed to Disappear? (Enquiry Concerning Electric Traction), 35
Argon, Chemical Properties of, 332
Armature Current, Effect of, on Magnetic Leakage, **248**
Armour Plates, Electric Annealing of, Prof. E. Thomson. **343**
Art Furniture Exhibition, 33
As Others See Us (Signor Semenza's Visit to English Electric Light Stations), 703
Association of Foremen Engineers, 465, 493
Association of Municipal Engineers, 494, **537**, 701
Athens Exhibition, 415
At Last (Construction of Berlin Electric Overhead Railway), 701
Atkinson, A. A., Opportunities in Electrical Engineering **600**, **630**
Australian Cable Contracts, 34
Awards, 61, 89, 118, 241, 301, 329, 545,

B.

Bailey, L. H., Electricity and Plant Growing, **51**
Baily, F. G., Scientific Foundations of Electrical Engineering, **307**
Baltic Canal, Electric Lighting of, C. Coerper, **706**
Baltimore Tunnel, Electrical Work in, 4
Battersea Polytechnic, 118, 273
Battery Inspection Lamp, **264**
Battery, New Non-Polarising Primary, 205
Battery, Vibration of, 673
Battle of Keely-Cranky (Keely Motor), 522
Beaumont, W. W., and S. Sellon, Parliamentary Procedure as Affecting Light Railways and Tramways, **287**
Bedell, F., and A. C. Crehore, Resonance in Transformer Circuits, **624**
Behind the Times (Direct-Connected Arc Light Station at Chicago), 33
Belfast Central Station, 93
Bell, L., The Monocyclic System, **346**
Berg, S. J., Mountain Railways, **52**
Berlin Elevated Railway, 212
Berlin Exhibition and Electricity, 581
Birmingham Technical School, 437
Black, C. N., Large Arc Dynamos, **402**
Blackburn Electricity Works, **185**, **226**
Blondel Lumen-Meter, **736**
Board of Trade New Electrical Regulations, **664**
Board of Trade and Transformer Chambers in London, 61, **74**, **77**
Boiler Explosions, Proportion of, per Annum, 702
Boiler and Machinery Repairs, Application of the Electric Arc System of Welding to, H. Foster, **196**, **218**
Bold Assertion (Daily Paper's Statement on Fate of Steam Railways), 581
Books, etc., Received, 1, 33, 61, 118, 302, 329, 413, 437, 466, 467, 521. 549, 581, 613, 627, 673, 701, 729
Bordeaux Exhibition, 2, 118, 466, 701
Borough Polytechnic, 2
Bournemouth Accident, 641
Bray (Ireland), Electric Lighting Bill, **379**
Brighton Corporation's Electric Lighting Accounts, **321**
Brighton Electric Call System, 385
Brighton Electricity Supply, Points of Interests in the Development of, A. Wright, **537**
Bristol Accident, **292**, 357
Bristol Electricity Works, **379**
British Aluminium Company's Proposed Works at Foyers, 238, 242, 304, 358, 382, 417, 441, 582, 696
British Association, 212, 301, 413, 549, 674
British Patents, Average Life of, etc., 494
Brush Central Stations, **155**
Brussels Central Station, 90
Brussels Exhibition. 357, 646
Building Trades' Exhibition, 209, 329
Bulet's Fire Alarm, 150
Bulkhead Door, Closing of, by Electrical Means, 582
Burglar Alarm, A Novel, 385
Business Changes, etc., 29, 176, 324, 461, 516, 546, 609, 668
Business During 1894, **18**, **47**, 87, 114, 115
Butters, C., and E. Smart, Extraction of Gold by the Cyanide Process, **217**

C.

Cable Jointing, New Method of, 210
Cable Rates to South Africa, 210
Cable Repairing, **111**, **133**, 195, 357
Cable Routes, Deputation to Lord Rosebery on, 617
Cable Steamer, Experiences of, 415
Callender-Webber Mains at Nottingham, **134**
Canadian Mica, 226, **255**, **345**
Canal Boats, Electric Power for, 360
Cannon-street Explosion, Major Cardew's Report on, **163**, **198**, **221**
Cantor Lectures on Arc Lamps, Prof. Thompson, 61, 64, 89, 91
Carbonnelle Microphone, The, **24**, 494
Carbons, Arc Light, B. F. Miles, **107**, **156**
Cardew, Major, Report on Cannon-street Explosion, **169**, **198**, **221**
Cardew, Major, Report on Southwark Bridge Explosions, **376**
Carlsruhe Exhibition, 673
CATALOGUES, ETC.: Baird, Thompson, and Co., 87; Britannia Company, 437; Cole, Marchant, and Co., 146; Cradley Boiler Company, 33; Dorman and Smith, 329; D. P. Battery Company, 640; Drake and Gorham, 150; Electrical Company, 33, 90, 466, 640; Electric Construction Company, 302; E. P. S. Company, 413, 438; Ernest Scott and Mountain, 209, 210; Hall, J. P., and Co., 181; Hayward Tyler and Co., 176; Hurst and Co., 465; Indestructible Ignition Tube Syndicate, 385; Johnson and Phillips, 302; W. J. Johnston Company, 1; Koch and Co., 241, 413; Laing, Wharton, and Down, 62; London Rustless Iron Company, 325; Luminous Enamel Syndicate, 112; Lundberg, A. P., 149; McGaw and Co., 34; Private Wire and Installation Company, 413; Safety Tread Syndicate, 324; Schuckert and Co., 494; Senator, S., 209; Straus, G., 415; Unbreakable Pulley and Mill Gearing Company, 324; Weiller and Co., 211; Wingrove and Son, 751
Causes of Explosions in Street Boxes, 244
Cawley, G., Method of Electric Traction for Tramways in Towns—The Thwaite-Cawley System, **745**
Ceiling Rose, New Detachable Double-Pole, **111**
Central-Station Engineers' Views on the Prevention of Explosions in Underground Mains, **94**, **124**, **154**, 211
Central-Station Libraries (Leading Article), **256**
Central Stations in France, 149, 212
Chambers of Commerce, Congress of, for 1896, 582
Change of Addresses, etc., 33, 85, 112, 176, 236, 353, 410, 433, 434, 462, 489, 546, 723, 751
Chelmsford Accounts (Leading Article), **687**
Cheltenham Electricity Works, **553**, **566**
Chemical Society, 273, 276, 359
Chesterfield and Midland Counties Institution of Engineers. 90, 303, 731
Chicago Edison Company's History and Work, 149
Chloride Accumulators, Manufacture of, 8
Chloride Storage Battery, Settlement of Litigation, 89, 119
Church Struck by Lightning, 33
City Athletic Club, 330, 357
City Guilds Examination (Leading Article), **597**
City and Guilds of London Institute, 90, **247**, 329, **468**, 496, 524
City and Guilds of London Institute and Solutions of Examination Papers, **452**, **475**, **505**, **536**, **539**, **597**, **598**, **715**
City of London Commission of Sewers Electrical Laboratory, **652**
City and South London Railway, 2, 33, 89, 385, 545
City and South London Railway (Leading Article), **74**
Clark Cell, Experiment on, when Producing a Current, 243
Closed-Coil Dynamos, Sparking of, G. T. Hanchett, **96**
Coal Consumption, Economy in, 332
Cock-and-Bull Story (Electrical Prevention of Collisions at Sea), 522
Code Cablegrams, 417, 440
Codes (Leading Article), **370**
Coerper, C., Electric Lighting of the Baltic Canal, **706**
Combined Electric Light and Waterworks, **259**
Commercial Cable Company's Hazell Hill Station, 676
Communication between Lighthouses and the Shore, etc., 2, 121, 150, 209, 210, 276, 301, 388, 550, 581
Commutators, Preparation for Cleaning, 61

Companies' Meetings, Reports, etc.:

THE

ELECTRICAL ENGINEER.

No. 1, Vol. XV. LONDON, JANUARY 4, 1895. PRICE 3D.

NOTES.

Underground Electric Railways.—An interview with Mr. Greathead on this subject appeared in the *Daily Chronicle* of Friday last.

Telephony in Germany.—It is intended to establish in the spring telephonic communication between Karlsruhe, Offenburg, Konstanz, Freiburg, and Lörrack.

Institution of Electrical Engineers.—The inaugural address by the president, Mr. R. E. Crompton, M.I.C.E., will be delivered on Thursday next, the 10th inst.

Technical Education.—Lord Playfair contributes a survey of the advance of technical education during the past 50 years to the first number of the *Polytechnic Magazine.*

Calendars.—We are in receipt of calendars for the current year from Messrs. W. H. Willcox and Co., Southwark-street, S.E., and from Mr. S. Howes, 64, Mark-lane, E.C.

New Book.—We have received from Mr. John Heywood "Calvert's Mechanics' Almanack and Workshop Companion" for 1895, this being the twenty-second year of publication.

Cable Rates to South Africa.—It is stated that the conference of representatives of the South African Governments, has resulted in an agreement for the reduction of the cable rates being decided on.

Electric Lighting in the Canary Islands.—Oratavo, in the Canary Islands, is lighted electrically, water power being utilised for the purpose. The plant has been supplied by a Swiss firm.

Personal.—Mr. E. Garcke informs us that his future address will be 1 and 2, Great Winchester-street, E.C.—Mr. J. T. Gent, of Messrs. Gent and Co., Leicester, has been returned as a member for the new Board of Guardians for Leicester.

Institution of Civil Engineers.—This institution, which was established on January 2, 1818, and incorporated by Royal charter on June 3, 1878, for the general advancement of mechanical science, now consists of 6,660 members of all classes.

Electric Traction in Russia.—The local authorities at St. Petersburg have objected to the scheme of electric tramways brought forward by Messrs. Barons, Pauli, and Co. A local horse tramway company, will, however, apply for similar powers.

Blotting Pad.—We have received from the Electrical Power Storage Company, Limited, 4, Great Winchester-street, E.C., a combined blotting pad, calendar, and diary, which is very useful in itself, and is an improvement upon that of last year. Particulars are also given of the manufactures of the company.

Competition.—Dr. Oliver J. Lodge has taken up a new line of writing. We have received No. 3 of the Liverpool Fabian Tracts, which consists of a pamphlet by Dr. Lodge entitled "Competition *v.* Co-operation," in which he argues that the supposition that competition is a good thing is "a deadly fallacy."

Madras Tramways.—According to *Indian Engineering*, it is said that the Madras Tramways Company has filed a suit against the Electric Construction Company, Limited, in England, for heavy damages on account of delay in completing the contract with respect to the construction of the Madras tramways.

Students of the Institution.—A students' meeting of the Institution of Electrical Engineers will be held this (Friday) evening at 28, Victoria-street, S.W. The business before the assembly will be the election of a representative committee, and discussion on the papers read recently before the Institution dealing with electric traction.

Electric Traction in France.—It is proposed to establish a line of electric tramways between Montluçon and Néris.—An electric tramway is to be constructed between Montiers and Brides-les-Bains, Savoy, power being obtained from two neighbouring waterfalls. It will be operated only from April 15 to October 15 each year.

Catalogue of Electrical Publications.—The W. J. Johnston Company, Limited, of 253, Broadway, New York, have sent us a copy of their catalogue of electrical publications. At the same time they notify that the "Digest" published weekly in the *Electrical World* will be extended, so as to include American technical literature.

Electric Light in Indian Jute Mills.—The Seebpore and Howrah Mills, Calcutta, are to be electrically lighted, and the installation in each case will consist of 1,300 8-c.p. incandescent lamps, the current being generated by three E.C.C. dynamos, each coupled direct with a steam-engine. The contracts were placed direct with home firms.

Lahore Durbar.—The electric lighting of the Viceregal camp at Lahore, says the *Indian Engineer*, has been undertaken by Messrs. Kilburn and Co., and the temporary installation has been erected under the personal supervision of their electrical engineer, Mr. Scott Moncrieff. The dynamos are driven by engines lent by the North-Western Railway.

Trunk Telephone Lines.—A new trunk postal telephone line between Leeds and South Wales has been opened to the public. The charges for three minutes' conversation is as follows: between Leeds and Aberdare, Cardiff, Merthyr, or Swansea, 2s. 6d.; Ebbw Vale or Pontypool, 2s. A postal telephone line has also been opened between Merthyr Tydfil and Newcastle-on-Tyne.

Machinery Under the Indian Tariff Act.—The Government of India are about to lay down an explicit definition of the term "machinery" for the purposes of the

Digitized by Google

levy of duty under the Indian Tariff Act of 1894. The question was raised in Bombay, and the Government of India have asked to be favoured with the opinion of the Government of Bombay and the Bombay Chamber of Commerce.

Telegraphy in India.—It is hoped to have another 120 telegraph offices opened during 1894-95. The Telegraph Department budget is now being prepared under the supervision of Mr. Brooke, director-general of telegraphs. It is impossible at present to say whether the budget will show a surplus, in face of the fact that the revenue from foreign telegraph despatches has decreased very considerably.

Electric Traction in Austria-Hungary.—Representatives of the towns of Crimmitschau, Meerane, and Glauchau have met and approved of a scheme for electric tramways proposed by Messrs. Siemens and Halske for connecting 19 neighbouring towns and villages.—Mr. Salesius Cathry has put before the local authorities of Budapest a project for an electric tramway between Ofner Brückenkopfe and Budakess.

Obituary in 1894.—In the course of a list of scientists who died in 1894 the *Times* includes the following: Prof. von Helmholtz, the great physicist; Prof. Heinrich Hertz, the eminent physicist of Bonn; Mr. Edwin Clark, the engineer and inventor of the block system of railway signalling; M. Paul Jablochkoff, the Russian electrician and inventor of the Jablochkoff candle; and Mr. Charles Arthur Redl, inventor of the dual system of signalling.

New Electrical Effect.—On New Year's Eve at the church of St. Mary-at-Hill, says the *City Press*, at five minutes to twelve "A Few More Years Shall Roll" was sung, during which the electric lights were gradually extinguished to represent the death of the old year. As the midnight chimes rang out a blaze of electric light in every part of the church announced the advent of 1895, "O God, our Help in Ages Past," being heartily sung by the large congregation, led by the rector's trombone, and assisted by a full orchestra.

Accumulator Traction in Vienna.—In a recent issue reference was made to a forthcoming trial of Waddell-Entz storage batteries for traction purposes in Vienna. It now appears that two accumulator cars on this system, similar to those operated recently on the Second-avenue surface road in New York, have been sent to Vienna, where they will be tested by a commission of representative electrical and civil engineers. The cars will be run on a line now worked by steam, and will thus be enabled to run at high speeds.

Electric Traction in Germany.—The tramway company of Strassburg, Alsace, intend to adopt electric traction on three of their lines. The work will be carried out by the Allgemeine Elektricitäts-Gesellschaft on the overhead trolley system, and it is expected that the lines will be in working order by May. A start will be made with 18 electric cars. Current will be obtained from the central electric light station.—The local authorities of Elberfeld have approved of a project by Mr. Langen for local electric lines.

Finsbury Park and City Electric Railway.—The Great Northern and City Railway Company, which was incorporated in 1892 for the purpose of constructing an electric railway from Finsbury Park to the City, have deposited a Bill for next session for the purpose of obtaining an extension of time from June, 1895, to June, 1897, within which to purchase the necessary land required for the railway. Consequent upon this extension, a further extension of time is sought until June, 1900, within which to open the railway for traffic.

A New Scare.—According to the Paris correspondent of the *Daily Chronicle*, the French Post Office authorities have received a communication from the Paris Faculty of Medicine setting forth the danger of spreading contagious diseases through the telephone. This, it is added, can be prevented by the use of a specially-prepared antiseptic paper. Diphtheria is said to be one of the complaints most easily propagated by telephone, and cases are said to have been traced to this cause amongst the women employed at the central and other bureaux.

Bordeaux Exhibition.—The Committee of Publicity formed by the London Chamber of Commerce in connection with this exhibition is informed that the South-Eastern and London and South-Western Railway Companies have agreed to the usual conditions for the carriage of exhibits—namely, full rates out and half rates home for exhibits returned unsold. The exhibition, which opens in May next and closes in the following November, is being organised and superintended by the Philomathic Society of Bordeaux. Intending British exhibitors desiring information should communicate with the secretary of the London Chamber of Commerce, Botolph House, Eastcheap, E.C.

New Publication.—Messrs. Whittaker and Co. inform us that they will issue to-morrow the *Technical World and Science and Art*, being the first number of a popular penny weekly. The new journal will embody the combined features of the *Technical World* and of *Science and Art*, two periodicals which have hitherto appeared as separate organs. It will appeal to all persons interested in the progress of art, science, and technology from an educational point of view, and its columns will be open to the discussion of all questions which may tend towards the improvement of methods of instruction. In addition to current news, the magazine will contain instructive articles by leading men in all the departments of pure and applied science and art.

City and South London Railway.—It will be remembered that the City and South London Railway Company have powers to extend their electric railway from Stockwell to Clapham, but this facility has not yet been taken advantage of. The Company have, however, now lodged a Bill for next session to obtain from Parliament an extension of time until July, 1901, for the purpose of completing this authorised extension. This extension, which is only 79 chains in length, was sanctioned in 1890, and an extension beyond the time originally granted was allowed by Parliament in 1893. The Company also seek power to raise £40,000 additional share and loan capital, of which £10,000 may be raised as debenture stock, and £30,000 as preference stock.

Borough Polytechnic Institute.—The Christmas conversazione in connection with the Borough Polytechnic Institute was held last week. The programme was extensive and varied, including concerts, limelight entertainments, photographic and art exhibitions, as well as electrical and telephonic exhibitions. A great source of attraction for visitors was the telephone department. Telephones were connected with half-a-dozen of the London theatres. Thirty pairs of receivers were at work, and in relays the visitors were afforded opportunities of listening to what was going on in these places of amusement. The institute has now about 2,300 members and over 100 educational classes, with numerous clubs and literary societies.

Electrical Communication with Lighthouses.—The Plymouth Chamber of Commerce last week had under consideration the subject of electrical communication with

Digitized by Google

lighthouses. Mr. R. Bayly proposed that a memorial be forwarded to the Board of Trade with a request that, following the recent stranding of the "Dunottar Castle" on the Eddystone reef, steps may be taken immediately to establish electrical communication between lighthouses and the shore. It was true that the Trinity House authorities had given notice of their intention to establish electrical communication between certain lighthouses and the shore, but at the present rate of progress the work, which might be accomplished in two years, would not be done in 20. The resolution was adopted.

Wolverhampton Electrical Engineering Works. The inauguration of active operations by Thomas Parker, Limited, according to a correspondent of the *Engineer*, seems likely to be rendered memorable by the invention of a new dynamo, for which great things are promised. Only one of the machines has as yet been made by the firm, and it is believed that it possesses important electrical developments. It includes the Eickemeyer patents, the more recent patents in connection with armatures, and new inventions by Thomas Parker, Limited, which have just been patented. The dynamo so far built will be used to light the whole of the works, both inside and out, but the design of which it is the earliest outcome will be regularly employed in the execution of orders.

Electric Traction in Italy.—The Municipal Council of Milan have extended for six months the concession granted to the Edison Company for the operation of the electric tramway carried out a year ago on the Thomson-Houston system from the Piazza del Duomo to the Via Semprone. The omnibus company are laying down electrical plant for the working of two lines on the same system. In order to shorten the railway journey between Benevent and Naples, Messrs. Niseo, Civita, and Caneva propose to construct an electric railway of normal gauge between Benevent and Cancello, *viâ* the Candina Valley. The line will be over 20 miles in length, and will pass through San Felice, Ariezzo, Arpaia, Airala, Montesarchio, Arpaise, and Appollosa, at each of which places there will be a station. Various bridges will have to be built over rivers.

Post Office Telegraphists. — The Postmaster-General on Tuesday received two deputations of telegraphists, the first consisting of 12 men, representing all classes in provincial offices; and the second composed of six delegates, representing metropolitan districts. The chief subjects submitted were the unsatisfactory methods of promotion in the service, inadequate pay, superannuation, and the system by which many telegraphists are compelled "to take their so-called holiday in the winter months." Mr. Arnold Morley, in reply, said he sympathised with their holiday grievance, but he could not hold out much hope of meeting them on the other points raised. He certainly was not prepared to recommend the abolition of classification. He gladly recognised the ability and moderation with which the delegates had stated their case.

Transmission of Power in America.—Referring to the return of Prof. G. Forbes to England on the completion of the Niagara transmission enterprise, the New York *Electrical Engineer* says: "During this anxious and critical time, Prof. Forbes has, of course, been in most intimate relations with the managers of the great enterprise, and now closes his professional engagement under terms of entire friendliness and cordiality on both sides. The advice and opinion of Prof. Forbes have been eagerly sought in regard to other plans of electrical power transmission, and we are glad to know that the revival of trade and industry, long looked for and not now far distant, may necessitate his further and early visits to this country. We should not be surprised to learn that as the result of observation or experience here, Prof. Forbes may, *ad interim*, see his way to the encouragement of smaller power transmissions in England, where there are no Niagaras, but many available waterfalls, to say nothing of coal mines near large cities."

Taxation of Machinery.—A striking illustration of the effect of taxing manufacturers for their machinery is afforded by the recent action of the Newcastle Assessment Committee in connection with the revaluation of the works belonging to Messrs. Armstrong, Mitchell, and Co., at Newcastle-on-Tyne, the magnitude of which perhaps exceeds that of any works to be found elsewhere in the hands of private manufacturers. The result of the valuation was to increase the rating to nearly £37,500. This sum having been appealed against, prolonged negotiations ensued between the Machinery Users' Association, acting on behalf of Messrs. Armstrong, Mitchell, and Co., and the union valuer which resulted in a compromise by which the assessment was reduced by £12,000 in the ratable value. The whole of this amount appears to have represented the value of the machinery and tools, but as the settlement was a compromise, it is possible that even now the machinery remains rated to a considerable extent. The above reduction represents an annual sum of about £3,000 which the firm would have had to pay really as a tax upon their machinery had the association not been able to obtain that amount of relief for them.

What is It?—A correspondent writes to the *Times*: "Mr. John R. Wigham, president of the Dublin Chamber of Commerce, has invented a new lighthouse light, and has brought it experimentally before the science department of the Royal Dublin Society. It may be briefly described as a method of making the illumination of revolving lights continuous, instead of as at present recurrent after intervals of darkness. A boon to navigation which mariners have very earnestly desired is that they might have the benefit of the great power and characteristic appearance of revolving lights, and at the same time have them continually in their eye, as are the fixed lights round our coasts. Mr. Wigham has had long experience in lighthouse matters, and this invention of his is considered the greatest advance which has been made in the science of lighthouse illumination since the time of Fresnel. Mr. Wigham's previous inventions, which have been adopted to a considerable extent by lighthouse authorities, have been mostly in the direction of conferring increased power on lighthouse illuminants. This new invention supplements those which he has previously made, inasmuch as it is applicable to all lighthouse lights—gas, oil, and electricity."

The Word "Scientist."—In the December number of *Science Gossip* a protest was entered against the use of the word "scientist," and opinions on the point have now been received from some well-known men. The Duke of Argyll, Sir John Lubbock, Lord Rayleigh, Prof. Huxley, and Dr. Albert Günther unreservedly condemn the word. Sir John Lubbock suggests the word "philosopher," Lord Rayleigh approves Lord Kelvin's proposal to revert to the wider meaning of "naturalist," while Dr. Günther sarcastically suggests that "scientist" might advantageously be reserved to denote the modern dabblers in great scientific questions. Prof. Huxley thinks "scientist" must be "about as pleasing as 'electrocution'" to anyone who respects the English language. Prof. A. R. Wallace alone views the word with composure; he even describes it as "useful," and argues that since we have "biologist," "zoologist," "geologist," "botanist," "chemist," "physicist," "physiologist," and "specialist," we might as well use "scientist." He asks what there is to use instead, and

Digitized by Google

expresses the opinion that it is too late to object to the word now. It is added by *Science Gossip* that the word was invented and explained by Whewell in his "Philosophy of the Inductive Sciences," 1840.

Electric Lighting in France.—The Municipal Council of Aix-les-Bains, Savoy, have decided to introduce the electric light.—The local authorities of Alais, Gard, have notified to the gas company their intention to introduce the electric light. The company have declined to exercise their right of priority, and, consequently, negotiations have been entered into by the municipality with Messrs. Louche, Bounefoi, and Froment.—The gas company of Angers, Maine-et-Loire, on the other hand, are asking for a concession for the electric lighting of the town. No decision has yet been come to, and in the meantime various private installations are being put up.—At Vire, Calvados, where the electric light was introduced two years ago, extensions of plant are to be made.—A concession has been granted by the municipality of Pornic, Loire-Inférieure, for the electric lighting of the town.—A central electric light station has been opened by the gas company at Saintes, Charente-Inférieure.—A new steam-engine of 100 h.p. will be added to the plant at the central station at Aubenas, Ardèche, by Messrs. Demange and Co., of Lyons.—The electric light is being introduced into Beaumont-de-Lomagne, Tarn-et-Garonne. The water power of the Gimone is utilised.—A limited company proposes to establish a central electric light station at Benzeville, Eure.

Current and Lines of Force.—The following rule, stated by Mr. B. S. Lampher in the New York *Electrical World*, gives the relation of the electric current to the lines of magnetic force produced by it: If you look at the positive (or north) end of an electromagnet, the direction of the current setting up the magnetism is that of positive rotation. Similarly, if you imagine a section made in a conductor carrying a current and look at the positive end of this conductor—*i.e.*, the end from which the current is flowing—the direction of lines of force set up about the conductor is the direction of positive rotation. Conversely, if you look at the negative (south) end of a solenoid, the direction of the current is that of negative rotation; and if you look at the negative end of a conductor—*i.e.*, imagine a section without really breaking the circuit—the direction of the lines of force about it will be that of negative rotation. Every student of electrical engineering knows that positive rotation, mathematically speaking, is opposite to the hands of a watch; and he also knows what is meant by the positive end of a magnet and the positive terminal of a conductor. Accordingly, if he remembers the rule at all, he cannot make a mistake like substituting "right hand" for "left hand," or "clockwise" for "anti-clockwise." It is a positive rule; positive end means positive rotation, and positive rotation gives a positive end.

Discussion of Papers.—Complaints have been heard here of the inadequate nature of the discussions on papers read on electrical matters, and in the current issue of the *Elektrotechnische Zeitschrift* an article appears in which attention is drawn to the same subject in connection with the German Elektrotechnischer Verein. It is pointed out that a thorough discussion upon a paper is the very thing which is required to make that paper of practical use for future work. Should a discussion fall entirely to pieces, there has been little use in the author reading the paper. He might as well present it to the members by simply printing it in the *Transactions* of the society. This course is, however, contrary to the *raison d'être* of a scientific society. The interest is not so much in the paper read, which is listened to usually in solemn silence, as in the personal exchange of opinions between the author and his hearers. The former should feel that the other members have given such consideration to his remarks that they are willing to contribute their experiences on the subject-matter, and even a sharp criticism, when confined to opinions and not personal, is preferable to an author than a silent reception of his paper. Two things are necessary for a good discussion: firstly, a proper grasp of the paper, which is obtainable by the circulation of advance proofs; and, secondly, the conquering of the timidity which, especially in the case of young members, makes them afraid to express their opinions before a large gathering.

A Large Alternator.—A large alternator, the great size of which has been rendered necessary by the conditions under which the machine is to be worked, and particularly the low speed, is now being constructed by the General Electric Company at Schenectady. This alternator, which is to be installed in the station of the Edison Electric Illuminating Company at St. Louis, Mo., will supply current for incandescent and arc lighting and for motive-power purposes. With a view to secure efficient results for these various uses, the generator is being constructed on the "monocyclic" system, which we recently described. This system employs a comparatively low frequency of alternations, and the armatures of the generators have special windings adapting them for use on circuits with self-starting current motors. The alternator in question is of 800 kilowatts capacity, has 80 poles, and is to be driven at 90 revolutions per minute. On account of the great size of the frame difficulties were expected in producing the castings, but owing to the facilities of the Schenectady works, no trouble was experienced in pouring even the large frame casting. This single piece, made up in part of wrought iron embedded in the castings, weighs 35 tons, and measures 24ft. over all. The armature is iron-clad and is 16ft. in diameter, weighing nearly 45 tons. The armature will be supported on a 22in. shaft. The generator will be able to supply, at full load, 667 amperes at 1,200 volts, or the equivalent of 16,000 16-c.p. lamps.

Electrical Work in the Baltimore Tunnel.—The Maryland Steel Company has secured the contract for making and erecting the overhead electrical equipment for use in the Baltimore (U.S.A.) Belt tunnel. Instead of using an overhead wire for the circuit, the General Electric Company, which is building the motors to haul Baltimore and Ohio trains through the tunnel, has decided to build an iron trough 1½ft. in circumference. A flexible wire will be attached to a shoe fitted into this ironwork, and will by this means carry the current to the motors of the engine. The purpose in using the hollow trough and the shoe is to avoid delays which may occur in the slipping off of the trolley wheel. Another advantage is secured in having a flexible wire for the electric connection instead of an upright iron pole, which does away with the necessity of shifting the pole every time it is desired to reverse the engine. The iron trough will be of heavy workmanship, and the work built to support it will be of light iron bridge construction. Iron poles will be placed 30 yards apart for that portion of the track inside the tunnel. On these poles will rest a framework of light iron, which in turn will support the trough. In the tunnel the trough will be near the centre of the tunnel roof. There it will be held in place by iron braces, also placed 30 yards apart, and fastened by bolts to the side of the tunnel arch. The overhead work will extend from Henrietta and Howard streets on the south to a point north of Huntingdon avenue, where the tunnel work of the Belt line ceases.

The Government and the Telephone.—A Newcastle paper says: "As is well known, the Government are now engaged in establishing telephonic communication throughout the country. According to the draft agreement laid on the table of the House of Commons, and to be submitted for approval in the coming session of Parliament, it is proposed to take over the trunk lines of the existing companies, but not to interfere with local services; and meanwhile other trunk lines are being provided. Some time ago the line between Leeds and Hull was opened, and similar means of communication between Leeds and South Wales are now available. The wire by which the latter is obtained, however, extends from the North-East of England to South Wales. Blaydon, Blyth, Durham, Hexham, Jarrow, Middlesbrough, Morpeth, Newcastle, North Shields, Ryton, South Shields, Stockton, Sunderland, and West Hartlepool, with Hull and Leeds, are now in direct communication with Aberdare, Barry Dock, Briton Ferry, Cardiff, Ebbw Vale, Merthyr, Newport, Pontypool, Swansea, Talywain, and Tonypandy. The wires laid down are of a specially large gauge, a thick wire being necessary for long-distance communication. The wires are of copper, and for the longest distances that used is nearly as thick as an ordinary lead pencil, weighing about 800lb. per mile. The cost will, therefore, not be of trifling amount. The Government are wisely determined, however, that the country's telephones shall be thoroughly efficient. So far the results are highly satisfactory. Trunk lines are now in course of construction from Leeds to London, Glasgow, Edinburgh, Belfast, Dublin, Manchester, and Liverpool, and these, along with those already in existence, will, so to speak, form the backbone of the Government system. The charges for conversations may at present be considered high—a three-minutes' talk between Blaydon and Cardiff, for example, costs 3s. 6d.—but the value of such a convenient, quick, and reliable means of communication, more especially to those engaged in commercial transactions, and where time is of importance, is not to be questioned."

Muzzle Velocity of Shot.—In the course of his first Cantor lecture delivered before the Society of Arts on "Explosives and their Modern Development," Prof. Vivian B. Lewes referred to the method of determining the muzzle velocity of shot which is effected by means of the chronograph. He said: "Two screens are arranged, one about 120ft. from the muzzle of the gun, and the second 120ft. beyond the first. These screens consist of wooden frames strung with fine copper wire, the disruption of a single strand of which is sufficient to break the flow of the galvanic current. In the Boulenge chronograph, a current from a battery of eight Bunsen cells flows through these wires and back to the instrument-house, where the wire from each frame is coiled round a separate soft iron core, and converts it into an electromagnet, each of which attracts and holds a rod of steel. The electromagnet in connection with the second frame is fixed at a lower level than the electromagnet connected with the first, and carries a short rod with a weight at the bottom, whilst the first magnet is at a much higher level, and carries a longer rod. The current being allowed to pass through both electromagnets, the rods are suspended in position. By pressing a key both circuits can be simultaneously broken, with the result that both the rods are liberated, and drop down guide tubes; the short rod strikes a catch, and causes a knife-edge to be brought against the longer falling iron, and to make a nick in it. When both rods are liberated simultaneously, this nick occurs at a definite place. The current is then allowed to pass, the rods hung on the electromagnets, and the gun containing the charge, the power of which is to be tested, is fired, the projectile passing through the screens and breaking the current by cutting the wires. Under these conditions the long rod is liberated a fraction of a second sooner than the shorter rod, the result being that the nick of the knife blade is no longer in the original place. By measuring the distance between the two nicks, and knowing the length of time to which this is equivalent, allowance being made for the time taken in liberating the knife blade, etc., the interval of time which elapses whilst the projectile is passing between the screens can be calculated, and, being corrected for the distance of the first screen from the muzzle, gives the muzzle velocity of the projectile."

Quantitative Analysis by Electrolysis.—In the *Berichte*, Mr. A. Classen gives a description, accompanied by plans and a sketch, of the manner in which the private laboratory and a bench in the inorganic laboratory are fitted up for electrolysis at Aix-la-Chapelle. At the bench 24 electrolyses can be simultaneously carried out, and the current in each electrolytic cell can be measured by means of an ampere-meter common to the set. The usual method of measuring the current with a gas voltameter before the electrolysis is commenced is very faulty. The author uses an ampere-meter, which can be thrown into circuit during electrolysis by adjusting a copper bridging wire between two mercury-cups. When the measurement is made, the bridge is removed and connection made so as to cut off the ampere-meter, but this time by means of a bridge having a resistance just equal to that of the meter; the current in the circuit thus remains equal to that at the time of measurement. The current is not quoted, but the current density, or the number of amperes per 100 square centimetres of surface of the electrode. The solutions used were commonly made by adding ammonium, or occasionally potassium oxalate, to a solution of the salt of the metal, some free oxalic acid being also usually added. In the case of antimony, however, sodium sulphide was added, and, in the case of silver, potassium cyanide. The deposits were dense and metallic. With lead, the electrolysis was carried out in the presence of nitric acid only, and the deposit of peroxide weighed as such. With manganese, it was done in the presence of acetic acid only, and the precipitate of peroxide was ignited and weighed as Mn_3O_4. In the case of mercury, tin, antimony, lead, and manganese, it was found expedient to use, not a polished platinum dish, but one the surface of which had been made matt by means of a sand blast; the deposit often adhered to this when it would not adhere to a smooth surface. Below are given details of current density in amperes, difference of potential of the electrodes in volts, temperature, and duration of the electrolysis as employed in depositing various metals.

	Current density, amperes.	Diff. of potential, volts.	Temp., deg.	Time, hours.
Copper	1·0-0·35	3·2-2·5	58-60	2-2½
Cadmium	1·0 0·5	3·4-2·75	68-76	3-3½
Zinc	1·0-0·5	4 8 3·5	55-60	2
Iron	1·5	3 4	20-15	½-¾
Nickel, Cobalt	1·0	3 0-3·5	60-70	2¼-2¾
Mercury	1·0 0·2	4·7 2 6	23·37	1½-5¼
Silver	0·5-0·2	4·8-3·3	20-30	1¾ 5
Tin	0·3-1·0	3·2 4·2	25-30	5¾-6½
Antimony	1·5-0·3	1·85-0·85	25 60	2-17½
Lead	1·65-1 45	2·5-2·4	60-65	1-1¼
Manganese	0 3	4·9-4·3	50-68	3

Similar details are also given for the separation of lead and copper, copper and iron, antimony from arsenic and from tin, copper from nickel and from cobalt, iron from aluminium and from chromium, and for the simultaneous deposition of iron and cobalt and of iron and nickel. The methods used are already well known.

IT WAS A DREAM.

It is often said that a man's dreams are as a rule connected with his waking thoughts, though the connection may in many cases be extremely indirect, if not absolutely topsy-turvy. I am afraid the latter condition must have held good in a dream that came upon me lately, after a long tussle with the things of to-day, but I would that it were otherwise.

On the occasion named, "me befel a ferly," as the old poet says: I dreamt that among the morning letters one day there was a polite note from the secretary of the well-known multi-millionaire, Mr. Roth Vander Astorschild, asking me to favour that already much-favoured gentleman with a call on the following afternoon at such and such an hour, with apologies for the short notice, etc., from "yours very faithfully." In the terms of the *Court Circular*, I was commanded to appear before the great commercial presence: and this I was in nowise loth to do, though the nature of the business at issue was beyond my imagination for the moment. When the appointed time came next day, however, and found me—after putting all else aside—in the magnate's waiting-room, I was soon enlightened, for the inner door had barely opened for me to pass through, when Mr. Astorschild gave a courteous salutation and plunged at once into business.

"You have," he said, "some knowledge of electric traction, have you not?" I modestly replied that it was and had been for long a matter of special study, but that the amount of my knowledge depended largely upon what was required therefrom. "What do you consider will be the course of developments in this branch during the early future?" he then asked. To this I replied that electrical engineers in general were hoping to see great progress made in the direction, not only of suitably converting lines (now worked by horses) for mechanical traction methods, but also of erecting and equipping a number of extensions to these, as well as many light railways all over the country; and for all such lines the use of electric energy as the motive power should have an excellent chance of adoption. "Why?" Because of its greater economy in point of first cost and working expenses, more particularly when the overhead wire or trolley system is employed. This method is under average conditions proved to be decidedly the cheapest, and, therefore, should be made standard. "Yes, I agree with you; this is just what I understand from the reports already made to me. Now, what is really being done to introduce and further the development of such a system on the English tramways?"

In reply, it was only possible to say that a few localities in the country were enterprising enough to take active steps in the matter; there were, for instance, Leeds, Walsall, Dublin, and Bristol, in all of which electric trolley lines were being worked or projected. "But what of London, the Metropolis itself? What is the use of beginning in the provinces: why not start at once in the headquarters of all the business and commercial life of the country?" I felt rather small on being forced to reply that London, of all places, was the very last where any efforts in this direction seemed likely to attain the least success. Not only had the County Council made up its mind (in absolute ignorance, it must be feared, of the true conditions or arguments on either hand) that overhead wires for such a purpose were equally iniquitous with sky-signs and telephone-wire networks, but the state of affairs in London at the present time in regard to tramway matters was an absolute deadlock that promised to endure for a generation at least.

"How many omnibuses are there now running upon the London streets?" I couldn't give exact figures, and merely voiced, in reply, the unanimous feeling of all who have ever thought of the matter, saying that there are just ten times as many as the streets will accommodate, but not one-tenth the number required to do justice to the traffic, simply because they can only travel at a snail's pace. "Does an electric tramcar, even when operated from an overhead conductor, take up any more room than an omnibus?" "Much less," I replied; "but the fact that they can maintain with perfect safety a much higher average speed would justify their existence on London streets, because so much fewer would be required for carrying on the traffic, even if individually they took up more room than omnibuses."

"Then we must get to work at once to build lines into the city from the principal suburbs. My brougham is continually being hindered by these crawling omnibuses when driving into the city, and I shall be glad if you will, on my behalf, take immediate steps to arrange the whole business ——" Here his voice became suddenly low and distant, whilst his figure grew very misty, and the whole room more like my own fireside, where I presently found myself a living dreamer with thoughts strongly proving the theory of association in ideas by comparison, for instinctively my mind had jumped to the happiest lot in life that it could imagine compared with the princely opening thus made with its attendant tasks and burdens. I woke up wondering how much Hodge was paid for breaking stones by the wayside.

K. N. A.

CONTROLLERS.

BY FRANK B. LEA.

Nothing could show more clearly the great difference between the condition of electric traction work in this country and the United States respectively than the fact that the word "controller" is at present a household term in the latter, whilst we only know it here in a restricted and narrow sense. There is probably not a street-railway manager or other official across the Atlantic who could not dilate upon the theory and characteristics of the controller as applied to the working of electric tramcars, whilst on this side, if the average tramway-man were asked what his opinions might be as to the best controller, his mind would doubtless revert at once to the dignified personages who preside over her Majesty's Patent Office and Board of Inland Revenue. Of course no injustice is intended, or is even possible to be done, in this connection to an excellent body of men; the fault lies in circumstances not having allowed any progress to be made in improved methods whereby new systems—and a new language—tend to arise.

Eight or ten years ago the pioneers in electric traction work were contented with a simple switch for cutting in or out the motor employed to drive a tramcar, and the idea of regulating the speed or the current passing through the motor was an elaboration of detail not yet thought of. Then the excessive starting currents and frequent burn-outs suggested the use of resistances, and these led to the employment of compound or multi-point switches for varying the resistances in circuit.

Finally, the late Anthony Reckenzaun conceived the idea of regulating the current by variations of the resistance of field-magnet coils, instead of or in addition to the use of artificial and extra resistances: and this plan, elaborated by Sprague and others, has proved the basis of a regulating appliance which combines all these advantages in a single and compact piece of apparatus, with the result that very great economies are effected in the capital outlay, in the amount of energy used for stated work done, and in the cost of repairs, labour, and renewals throughout the fixed and movable plant of an electric tramway. The controller is to-day something more than a regulator of current: its employment has literally controlled—in the sense of fostering—the development of electric traction, and the man who "twists the handle" has a piece of mechanism under his charge that is most essential to the well-being of the entire system.

The controller in its present form is, however, perhaps not altogether perfect, though to examine one is sufficient to show the enormous progress that has been made upon early devices. In essence it consists of a series of contacts arranged cylindrically or in barrel shape upon a vertical axis, which is rotated by means of a handle. Its angular movement effects changes in the contacts, so that, beginning from the cut-off position, the motors are switched in in series one with the other, and with a resistance; then, the latter is cut out and again cut in in series with the motors that are now in parallel, the action tending to regulate the current in

Digitized by Google

accordance with the car speed. Of course, the total movement is much less than the complete circle, a reverse motion of the handle being used in stopping the car. To reverse the *direction* of the latter, a separate reversing handle at the side of the controller stand is usually employed. A motor switch overhead and the ordinary brake handle complete the regular equipment of an electric tramcar, and it may be thought that the motorman will find plenty to do in properly looking after his operating gear. This leads to the consideration of other possible forms of controller gear.

For ordinary or service stops, there is not in any way too much for an intelligent motorman to do. He simply runs the controller handle back, cuts off the current, and twists the brake handle. Emergency stops, however—which are just the occasions when men get rattled, although usually of iron nerve—require, it may be, the reversing lever to be thrown over, and in the hurry to do three things at once the chances may be that none are carried out properly. The possibility of the controller handle being turned or kept in the wrong direction has led some to advocate a form of switch gear with a fore and aft straight line motion, just as in steam-locomotive work the lever reverse gear is much preferred in certain cases to the use of a screw, if only to prevent mistakes. Trouble may be partly avoided by so interlocking—as is now usually done—the reverse lever and controller spindle that the current through the motors can only be reversed under suitable conditions, but there is much to be said for an action of the controller gear which shows in itself what the attendant result will be. This course is usually followed with cable cars, and might be considered yet again for electrical working, though the valuable compactness of a cylindrical controller would be almost entirely lost.

PROGRESS OF THE ELECTRIC TELEGRAPH.

Although little more than half a century has elapsed since the first telegraph line was opened in Europe, recent statistics, says the *Times*, show that telegraphy has made astounding progress. Germany can claim the honour of being the first country in which a telegraph line was opened. This was in 1833, and four years later Cooke and Wheatstone made their first successful effort in England with the telegraphic communication between Euston and Camden Town, on the London and North-Western line. The first telegraph line really set up in England, however, was that between Paddington and West Drayton, on the Great Western line, which was established in 1838. The United States succeeded in 1844, and then came in the following order Belgium, Austria, Italy, France, Holland, Switzerland, Sweden, Russia, Denmark, Norway, and Spain. Selecting the year 1870 as an example for the despatch of messages, we find that the smallest number despatched was 466,700 by Norway, and the largest, 9,350,000, by Great Britain. Germany had already fallen to the third place in the list with 8,207,800 messages, the United States being second in the list with 9,157,646. Twenty-two years later (1892) Norway had still the smallest number of messages carried—namely, 1,649,544. Germany was now fourth in the list with 31,175,100. No figures were forthcoming for France in 1892, but in 1891 the number of messages carried in that country was 32,397,000. The United Kingdom still retained the first place, its total in 1892 being 69,908,600, compared with 62,387,298 in the United States. Austria held fifth place in 1892 with 10,835,302, and Italy seventh with 8,322,925. With regard to the proportion between the number of messages carried and the population, in 1870 Russia was lowest on the list, the messages being only 0·04 per head of the population. Next in rank to Russia, as being the lowest on the list with regard to the proportion of telegrams to population, in 1870, were France, Italy, Sweden, Spain, and Hungary; but since then France has made great strides, and is now among the first five countries, having increased from 0·1 to 0·9. Switzerland was first in 1870 with 0·6 message per head, but the United Kingdom took first place in 1892 with 1·8 per head.

THE FUTURE OF ELECTRICITY.

BY SYDNEY F. WALKER.

Whenever one engages in conversation with anyone not in the ranks of electrical engineering, it rarely happens that one's friend does not remark very early in the conversation that "electricity is still in its infancy," usually prefacing the observation by the statement that he personally knows nothing of the subject. The observation has been made so often that one really becomes very tired of its incessant repetition, and we feel strongly inclined to beg our friends not to repeat the old saying too often. Yet after all, when we consider the question, is it not true in spite of what has been done during the last 60 years, and particularly during the last 20?

Judged by the age of other branches of science electricity is still an infant, with all its manhood's work yet to accomplish—work that none who are now its servants can hope to take part in; work that few of us can even venture to foretell. It is by the use of steam and of electricity that the modern world of the nineteenth century is distinguished from the older worlds that have gone before. What might not those mighty races of bygone ages have accomplished had they been blessed with such servants as these? And even now, while steam is young, as the universe judges time, the handwriting is on the wall, not, as at the Eastern monarch's feast, in strong condemnation of the empire that is passing away—for steam has been a faithful servant, and will be for many years to come—but as a warning that its days are numbered, nevertheless. And may it not be also in the future that even the young giant we serve, whose infantile deeds are so prodigious, will have to give place to another agent as yet unknown? If it be that electricity and electromagnetism, with sound, light, and heat, are merely varying forms of the same thing, varying rates of molecular motion, can we suppose that there are not other rates of motion possessed of other properties possibly still more wonderful than those that have surprised the present generation? Between the molecular motion we know as sound and the slowest of the motions we know as invisible heat, there is room for many other rates.

But what may we hope for in the future from electricity itself? First, then, the gradual utilisation of the forces of Nature known as wind and water power, to the gradual displacement of power from the combustion of coal. At irregular periods the world is startled by the cry, What will become of us when our coal fails? We are turning out an increasing number of millions of tons yearly, and the supply is limited. We are squandering our national wealth. What is to become of us as a manufacturing nation? Long before the supply of coal approaches exhaustion its price will increase and our other industries will be crippled. What are we to do? The reply is, in my opinion, that long before the price of coal rises from this cause coal itself will have to fight for its life as an industrial product, just as gas is now doing, the antagonists being wind and water power, delivered where required by the aid of electricity.

And what about gas? Only twelve months since it was safe to prophesy, as far as could be seen then, that gas was doomed to extinction at no distant period. The perfection and adoption of the Welsbach incandescent gas-burner will probably give it a new lease. If the Welsbach apparatus becomes universally adopted, and the gas companies are able to carry out their threatened revolution, the supply of a heating gas only—necessarily a much cheaper gas—electricity will have received a very serious set-back, the most serious it has received during the last 20 years. Once the price is reduced, gas will be used much more for heating and for power than it is now, and while at present the running cost of an incandescent lamp is twice that of an ordinary gas-burner in any district, and power costs four times as much when taken from any town's electric supply mains as it costs when taken from the gas service, the proportion when cheaper gas is supplied will be very much greater. But a little consideration will show that the set-back will be only temporary, can be only temporary, unless electrical engineers alter very considerably during the next few years. The principle of the Welsbach burner,

Digitized by Google

or its equivalent, must be adopted in the electric incandescent lamp of the future. In the Welsbach burner we have a substance capable of withstanding a high temperature with the necessary heat applied to the substance from outside by means of the combustion of gas. When electric lamp-makers find a substance that will stand very much higher temperatures than the present incandescent lamp filaments do, the Welsbach burner will again have to take a back seat, and electricity will have made another stride, and a very long one, in its progressive fight with its rivals, since in addition to reducing the running cost of the lamp itself, its greater efficiency will enormously increase the earning power of the plant and cables.

In the matter of power, too, the gradual education of consumers in the use of higher voltages will gradually decrease the running cost. There is one use of electric power, however, for which the present outlook does not seem very hopeful—viz., for tramcar driving.

Notwithstanding all that has been done in America, and the special cases in this country where electricity has been successfully employed, apparently it must be some years, many years, before it can be generally applied to the ordinary street service, unless some unforeseen discovery should be made very shortly. America is not England, and the Black Country is not England; and no matter what may be tolerated there, no English town of importance would be likely to allow the hideous arrangements necessary for the overhead system in any of its principal thoroughfares. The conduit system and the accumulator system await the march of invention. Both are barred by the excessive cost of running.

Heating by electricity, though only recently introduced, has already made rapid strides; and although where the current to be used for heating is taken from the town supply the cost is still so excessive that it can only be regarded as a luxury, yet there are now many cases where the extra convenience is well worth the extra cost, and there will be many more as time goes on, and as the natural development of the lighting industry produces the usual effect—viz., gradual reduction of cost.

Telephones are daily becoming more and more used, and hence more and more useful. The future for them should mean still further usefulness by reason of more perfect service. In the future, too, we may hope to have communications by telephone without wires. Shall we also see by electricity without wires? In mining and general industrial work, the progress of electricity in the past and the hopes for its future leave nothing to be desired.

Whether Messrs. Thwaites and Swinburne's idea of burning the coal and the gas generated in coal mines at the pit's mouth, and distributing to centres of industry, is ever realised will depend on how soon the developments of wind and water power are made. Possibly some such scheme may come in to assist coal in its battle, in the same way that the Welsbach burner has come in to assist gas now.

Local conditions, too, will largely rule whether coal, wind, or water shall be used, since the initial outlay will be approximately the same, and the voltages used may be the same. But, since for both the economical consumption of coal at large centres and the utilisation of wind and water power, high voltages will be necessary, and the higher the voltage that can be employed the more economical will be the working of the system, may not engineers indulge in a yet bolder dream?

The dream of ages, the utilisation of the gigantic energy of Niagara, is now, in part at least, an accomplished fact; is it too bold to dream of using the energy of the agent that creates Niagara, the sun itself, by the aid of electricity, to neutralise some of the effects created by the absence of the sun's rays? Daily, hourly, the whole year round, enormous quantities of energy are delivered directly to the earth, within the tropical zone, yet during the whole year large tracts of land are rendered absolutely valueless to man owing to the want of the heat so abundant in the tropics, while even yet larger tracts are deprived of a considerable part of their fertility from the same cause. Is it too bold a dream to imagine a portion of the superfluous heat of the tropics delivered within the icebound regions by the aid of electricity? What would our ancestors have thought if anyone had foretold in their days the present use of Niagara?

Once more, too, if what we know as electricity be a form of molecular motion at a lower rate than the slowest of the invisible heat waves, the day on which it becomes possible to reduce the rate of the molecules, when vibrating under the influence of heat, directly until their motion corresponds with the rate we know as electricity without the at present necessary repeated transformations, an enormous stride will have been made towards neutralising the inequalities of climates on our globe. And there is even yet another manner in which we may hope that electricity may help us in our battle with the inequalities of Nature.

It is now some years since Lord Rayleigh discovered that the large raindrops we are so familiar with in thunder showers are due to the electrification, and consequent aggregation, of the fine particles of moisture present in the atmosphere. It is also some years since Prof. Oliver Lodge added to Lord Rayleigh's work the discovery that floating dust particles might be aggregated in the same manner as the raindrops are by discharges of static electricity. Yet beyond an apparently crude experiment on lead dust, no use has been made of either of these brilliant discoveries.

Is it too bold, wickedly bold, to hope that in the future by means of electricity we may be able, at least in part, to control our seasons? Why need we have a dry summer, as in 1893, when the moisture is present in the atmosphere, and can be made to descend? Why need we have superlatively wet seasons if the atmosphere is not allowed to retain a superabundance of moisture, when it may be caused to discharge its cargo when desired? Why should not our Government vote a large sum to working out these problems? Can we doubt that if the discoveries had been made by French physicists the French Government would not have given every assistance, instead of standing coldly by, supremely indifferent until the time arrived when the discovery may bear taking? Is it too much to hope that the coming year may see some little thing done in this direction?

THE MANUFACTURE OF CHLORIDE ACCUMULATORS.

In our last issue we referred to the acquisition by the Electric Storage Battery Company, of Philadelphia, the owners of the chloride accumulator patents, of all the fundamental storage battery patents in the United States. In this connection it is interesting to note that the chloride battery which has been introduced in England by the Electrical Storage Syndicate, Limited, of 16, Victoria-street, S.W., forms the subject of an illustrated description in the New York *Electrical Engineer* of December 19, from which the following is abstracted.

Homogeneity in the active material is a *sine quâ non* of a successful storage battery plate, and while spongy lead may be reduced from a number of different lead salts, there are but comparatively few that are at all suitable for storage battery purposes, and among these the chloride of lead has been found by the company after a long series of experiments to be the best adapted. In order to be certain of the purity of its working materials, the company itself from the very start undertook the manufacture of the chloride of lead, and developed special processes to that end. The first step in the production of the chloride consists in reducing commercial lead to a fine powder, which is accomplished by directing a blast of compressed air against an orifice from which issues a fine stream of molten lead. The result is a spray of lead which cools and falls as a powder. The lead finely divided in this ingenious way is next dissolved in nitric acid and then precipitated as chloride of lead by the addition of hydrochloric acid. The white chloride of lead, after being thoroughly washed and dried, forms the basis of the material which subsequently becomes active in the battery plate, and as such its production is carried on with the greatest care and supervision to prevent the introduction of impurities.

Digitized by Google

The casting-room contains two large furnaces, in which the chloride of lead, mixed with a certain proportion of chloride of zinc, is brought to a molten state. These crucibles are heated by a furnace in which crude petroleum is burnt by means of a steam spray blast. The pastilles which subsequently form the active material of the battery are cast in a mould, the metal being ladled out by the workman. These pastilles are not poured solid, but the mould is so arranged as to leave them with a hole in the centre, by which they are subsequently located and held in position in the casting frame of the lead mould.

To those who have witnessed the old method of pouring lead storage battery grids by hand, the method here adopted will prove a source of much interest. Instead of the old slow and somewhat uncertain method the arrangement adopted is the forcing of the lead into the grid under pressure of 75lb. to 180lb. per square inch, depending upon the size of the plate, filling the mould completely, and leaving no chance for blow-holes. The chloride pastilles are placed in the mould, being held in position by pins projecting through the holes provided at their centres. The mould is then introduced into the lead-casting press, a turn of the handle opens the valve leading to the lead furnace, and a turn of a second valve admits the air pressure, which forces the lead into the mould. The entire operation requires less time in its performance than that occupied in describing it here, and the result is a grid firmly grasping the pastilles. The lead employed has a slight addition of antimony to aid in giving it stiffness and non-corroding properties. The two furnaces have a capacity for casting 10 tons of battery plates per day. After they leave the press, the plates are finished and scraped smooth, and are now ready for the next process—that is, the reduction of the chloride.

The plates are stacked by alternating each lead plate with a slab of zinc, all immersed in tanks filled with dilute chloride of zinc. The plates so assembled constitute, in fact, a primary battery, and by short-circuiting them the chloride of lead is reduced. The chlorine leaving the pastilles forms chloride of zinc, and the pastille is finally reduced to crystalline lead. After the reduction is complete it only remains to wash the plates thoroughly in running water in order to remove the last traces of zinc chloride. The reducing process occupies about 48 hours. The reduced plates are now assembled and have the lead connecting lug burnt on them by means of the hydrogen flame. The plates that are intended for the negatives of the cell require no further treatment, as they contain the pure spongy lead, but those designed to act as anodes or positives must, of course, undergo treatment to convert the spongy lead into the peroxide. The plates, immersed in tanks filled with dilute sulphuric acid of the proper strength, receive a continuous charge of two weeks' duration in one direction, which thoroughly converts the spongy lead into peroxide. The current for forming the plates is furnished by one 500-ampere and two 200-ampere machines of 125 volts each.

With the peroxide completely formed the positives and negatives are now ready to be assembled. In order to ensure the integrity of each individual plate, special means are provided in the chloride cell for maintaining the plates of opposite polarity separate from one another, and for this purpose each positive plate is first covered on both sides by a sheet of asbestos cloth. In addition to this, however, a further stiffening is obtained by the introduction of a partition of cherry wood, which is perforated by numerous holes, the perforations being connected by grooves so as to admit of the free circulation of the electrolyte. The output of the company's factory embraces a wide range of sizes, and the purposes for which the cells are used are equally numerous. Thus, in one of the rooms we note the 1,000-ampere-hour cells, which will be shortly installed in the Edison Illuminating Company's station in New York. At another point we see cells made up into portable groups of two, three, and more for electro-medical purposes, and at another we find a case designed as a portable outfit for a theatrical company, and again sets of small cells 2in. by 4in., containing three plates, intended to be used in connection with long-distance telephone sets.

PRACTICAL NOTES ON DYNAMO CALCULATION.*

BY ALFRED E. WIENER.

(Continued from page 745, Vol. XIV.)

39. *Relative Permeances in Dynamo-Electric Machines.*—(*a*) *Principle of Magnetic Potential.*—In taking the magnetic potential between two pole-pieces of opposite polarity as unity for calculating the relative permeances in dynamo-electric machines, the potentials between various points of the magnetic circuit depend upon the number of electromagnets magnetically in series between two consecutive poles of opposite polarity.

If, as is the case in the majority of types, there are two magnets between any north pole and the next south pole of the machine, then the magnetic potential between two points, x and y (Fig. 57), of the magnetic circuit separated by but one electromagnet is $=\frac{1}{2}$; and two points, y and z, of the magnet frame not separated by any exciting coil, have no difference of magnetic potential, their potential $=0$. If the circuit consists of but one electromagnet, or of several magnets magnetically in parallel, then the magnetic potential between any two leakage surfaces of opposite polarity is $=1$—*i.e.*, equal to the difference of magnetic potential between the pole-pieces.

The observance of this general principle enables us to bring all the relative permeances into proper relation to each other, and we can now apply formulæ (112) to (118) to the cases of a dynamo.

(*b*) *Relative Permeance of the Air-Gaps* (P_1).—According to (112) the relative permeance of the air-gaps can be expressed by

$$P_1 = \frac{A_g}{l_g} \quad . \quad . \quad . \quad . \quad . \quad . \quad (119)$$

if A_g = area of gap spaces—*i.e.*, the mean of pole area and surface of armature core in square inches—(see formula (120),

and l_g = mean distance between pole-pieces and armature circumference in inches (see (124) and (125).

The mean area of the gap space for any armature facing poles opposite its outer periphery is given by the equation:

$$A_g = \tfrac{1}{2}(a_a + a_p) \times \tfrac{1}{2}(l_a + l_p) \quad . \quad (120)$$

where a_a = half perimeter of armature core, in inches.

For smooth cores, Fig. 58:

$$a_a = \frac{d_a \times \pi}{2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (121)$$

for toothed cores, Fig. 59:

$$a_a = \frac{d_a \times \pi}{2} + n \times q \quad . \quad . \quad . \quad (122)$$

d_a = diameter of armature core, in inches;
n = number of teeth;
q = depth of slots, in inches;
a_p = circumference of half the pole-pieces, in inches;

$$a_p = d_p \times \pi \times \frac{P \times \phi}{360^\circ} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (123)$$

d_p = diameter of bore of pole-pieces, in inches;
p = number of pairs of magnet poles;
ϕ = angle embraced by each pole;
l_a = length of armature core, in inches;
l_p = length of pole-pieces, in inches;

The mean length of the field path, in both gaps, according to Chapter 48, is—

For smooth armatures:

$$l_g = k_{13} \times (d_p - d_a) \quad . \quad . \quad . \quad (124)$$

and for toothed armatures:

$$l_g = k_{13} \times (d_p - d_a) + \frac{s \times q}{s + t} \quad . \quad . \quad (125)$$

d_a = diameter of armature core, in inches;
d_p = diameter of bore of field, in inches; } Figs. 58 and 59
s = width of slots, in inches;
t = width at top of teeth, in inches; } Fig. 59.
q = depth of slots, in inches;
k_{13} = factor of field deflection (see Table LVI. in Chapter 48).

* From the *Electrical World* (New York).

Digitized by Google

Combining formulæ (120), (121), (123), and (124), and formulæ (120), (122), (123), and (125) respectively, the relative permeance of the air-gaps for smooth and for toothed armatures respectively is obtained.

For smooth armatures we have :

$$P_1 = \frac{A_g}{l_g} = \frac{\frac{1}{2}\left(\frac{d_a\pi}{2} + d_p\pi \times \frac{p+\phi}{360^\circ}\right) \times \frac{1}{2}(l_a + l_p)}{k_{13} \times (d_p - d_a)}$$

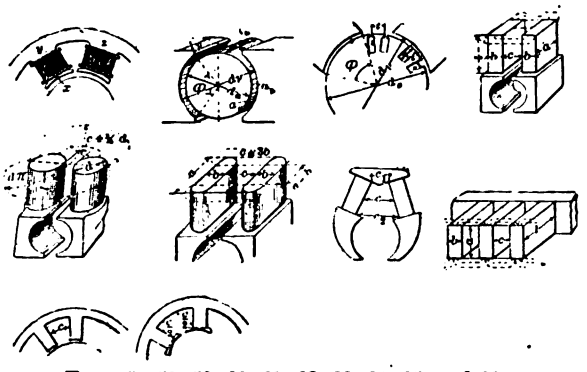
$$= \frac{\left(\frac{1}{8} d_a\pi + d_p\pi \times \frac{p \times \phi}{180}\right)(l_a + l_p)}{k_{13} \times (d_p - d_a)} \quad . \quad (126)$$

and for toothed armatures :

$$P_1 = \frac{A_g}{l_g} = \frac{\frac{1}{2}\left[\left(\frac{d_a\pi}{2} + n \times q\right) + d_p\pi \times \frac{p \times \phi}{360^\circ}\right] \times \frac{1}{2}(l_a + l_p).}{k_{13} \times (d_p - d_a) + \frac{s \times q}{s+t}}$$

$$= \frac{\frac{1}{8}\left(d_a\pi + d_p\pi \times \frac{p \times \phi}{180} + n \times q\right)(l_a + l_p)}{k_{13} \times (d_p - d_a) \times \frac{s+q}{s+t}} \quad (127)$$

For armatures revolving outside of a magnetic field (inner-pole type), in the denominator of formula (125) the order of the diameters d_a and d_p is to be reversed, as in this case d_a, the internal diameter of the armature core, is larger than the diameter of the field.



Figs. 57, 58, 59, 60, 61, 62, 63, 64, 65, and 66.

If poles are situated interior as well as exterior to the armature, the mean of the outer and inner gap areas has to be taken by applying formula (120) to the inner diameter as well as to the outer diameter of the core, and instead of $(d_p - d_a)$ the sum of the outer and inner gaps is to be substituted.

In case of armatures, finally, facing the poles in the axial direction (flat ring type), the gap area, if pole-pieces are used, is the mean of half the pole area and the ring area of the armature core, and if no separate pole-pieces are employed is practically equal to half the sectional area of the magnet cores. The mean length of the path is the difference between the axial pole-distance and the axial breadth of the armature core multiplied by the factor of field deflection.

(*c*) *Relative Average Permeance Across the Magnetic Cores* (P_2).—Since in dynamo-electric machines the magnet cores with their ends averted from the armature are magnetically joined by special "yokes," or by the frame of the machine forming the magnetic return circuit, the magnetic potential between these joined ends is practically = 0, while the full magnetic potential is availing between the free ends towards the armature. The average magnetic potential over the whole length of the magnet cores, therefore, is one-half of the maximum potential, and the average relative permeance, consequently, one-half of that which would exist between the cores if they had the same magnetic potential all over their length.

For the various forms of magnetic cores by means of formulæ (113) to (118) respectively, we therefore obtain the following relative average permeances :

1. *Rectangular Cores.*—The permeance between two rectangular magnet cores, Fig. 60, is the sum of the permeances between the inner surfaces which face each other, formula (114), and between the end surfaces which lie in the same plane, formula (115), and therefore the average permeance is

$$P_2 = \frac{a \times l}{2c} + \frac{b \times l}{c + b \times \frac{\pi}{2}} \quad . \quad . \quad . \quad (128)$$

where a, b, c, and l are the dimensions of the cores, in inches, as in Fig. 60.

2. *Round Cores.*—According to formula (117) we have in this case (see Fig. 61) :

$$P_2 = \frac{1}{2} \times \frac{d\pi \times l}{c + \frac{3}{4}d} = \frac{d\pi \times l}{2c + 1{\cdot}5\,d} \quad . \quad . \quad (129)$$

3. *Oval Cores.*—For oval cores, Fig. 62, the permeance path consists of two parts—a straight portion between the inner surfaces, and a curved portion between the round end surfaces. Combining, therefore, formulæ (114) and (117) we obtain :

$$P_2 = \frac{(a-b) \times l}{2c} + \frac{b\pi \times l}{2c + 1{\cdot}5\,b} \quad . \quad . \quad (130)$$

4. *Inclined Cores.*—If the cores, instead of being parallel to each other, are set at an angle, Fig. 63, the distance c in formulæ (128), (129), and (130) respectively has to be averaged from the least and greatest distance of the cores:

$$c = \frac{c_1 + c_2}{2} \quad . \quad . \quad . \quad . \quad (131)$$

5. *Multipolar Types.*—In the case of multipolar dynamos of p pairs of poles, the total permeance across the magnet cores is $2p$ times that between each pair of the cores. In calculating the latter, it has to be considered that while the permeances across two opposite side surfaces does not change by increasing their number, the leakage across two end surfaces is reduced—half of the lines leaking to the neighbouring core at one side, and half to that on the other side.

For rectangular cores, therefore, we have, with reference to Fig. 64 :

$$P_2 = 2p \times \left(\frac{a \times l}{2c} + \frac{\frac{1}{2} b \times l}{c + b \times \frac{\pi}{4}}\right) = p \times \left(\frac{a \times l}{c} + \frac{b \times l}{c + b\frac{\pi}{4}}\right) \quad (132)$$

For round cores, according to formula (118) :

$$P_2 = 2p \times \frac{d\pi \times l}{2(2c + {\cdot}6\,d)} = p \times \frac{d\pi \times l}{2c + {\cdot}6\,d} \quad . \quad (133)$$

and for oval cores :

$$P_2 = p \times \left(\frac{(a-b) \times l}{2c} \times \frac{b \times \pi \times l}{2c + {\cdot}6\,b}\right) \quad . \quad . \quad (134)$$

In multipolar machines, for c the smaller of either the mean distance between two magnets, Fig. 65, or twice the mean distance between magnet core and yoke, Fig. 66, is to be taken.

(*d*) *Relative Permeance Across Pole-Pieces* (P_3).—The amount of leakage across the end and side surfaces of the pole-pieces—that is, across all their surfaces not facing the armature core—depends upon the slope of the pole-pieces, and upon the design of the machine with reference to an actual iron surface (bedplates) near the pole-pieces.

By the principle of the magnetic potential the actual permeance, according to formula (112), in this case is also the "relative" one, as the magnetic potential between two pole-pieces of opposite polarity is unity.

The respective relative permeance for the various shapes of pole-pieces can, therefore, easily be deduced by means of formulæ (113) to (118), Chapter 38.

(*e*) *Relative Permeance Between Pole-Pieces and Yoke* (P_4).—According to the general principle of calculating relative permeances, the magnetic potential between pole-pieces and yoke is to be taken = ½, with reference to the potential between two pole-pieces of opposite polarity; for the yokes serve to join two magnet cores in series magnetically, and are therefore separated from the pole-pieces by but

Digitized by Google

one electromagnet. If the yokes join the magnets in parallel, then they usually serve as pole-pieces also, and must be considered as such in leakage calculations.

Since the amounts of the leakages in the various paths are proportional to their permeances, in dynamos having an external iron surface near the pole-pieces, most of the leakage takes place between the pole-pieces across that external surface, and in such machines the leakage from the pole-pieces to the yoke is comparatively small.

The value of the relative permeance between pole-pieces and yoke for every individual case, consequently, is obtained by taking one half of the respective actual permeance as calculated from formulæ (112) to (118) respectively.

NOTE.—The end of Chapter 36, page 744, should read: "Prof. Forbes's logarithmic formulæ* heretofore employed," etc.

Formula (113), page 744, should read:

$$P = \frac{\frac{1}{2}(A_1 + A_2)}{c + \frac{a_1 + a_2}{2} \times \frac{\pi}{2} \times \frac{a}{180^\circ}} \quad . \quad . \quad (113)$$

In paragraph referring to Fig. 54, section (*e*), page 745, $y = \frac{a}{4}$ should be replaced by $y = \frac{d}{4}$.

In section (*f*) of page 745, read $c + \cdot 3\ d$, instead of $C + \cdot 3\ d$.

(To be continued.)

ON THE PRODUCTION OF ROTARY MAGNETIC FIELDS BY A SINGLE ALTERNATING CURRENT.†

BY LUDWIG GUTMANN.

Since the first announcements of Prof. Ferraris and Mr. Tesla, that rotation can be accomplished by employing two or more alternating currents of displaced phase, the question has been raised by many an engineer as to the possibility of producing a rotary magnetic field by the use of a single circuit, carrying the ordinary alternating current, instead of requiring three or more wires or several independent circuits. So far, it has been necessary to construct a special generator armature, the windings of which were rotated in a field of constant polarity, to produce two or more currents lagging in phase behind each other. To use the currents generated for establishing a progressive or rotary field, it was necessary to carry as many wires to the place of consumption as currents were employed differing in phase. Six years have passed, and quite rapid progress has been made in various directions. I wish now to bring to your notice a method of generating a rotary magnetic field by a single alternating current or its field, without condensers or choking coils. This is accomplished by a device brought out by me some three years ago. Its fundamental principle is hardly as yet appreciated; however, the World's Fair exhibits, as well as literature of late, show that the device has attracted attention, and that several engineers have approached the principle involved.

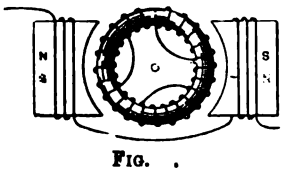


FIG. .

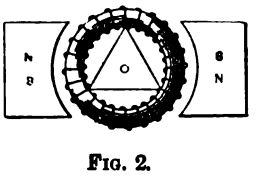

FIG. 2.

I wish to refer to my motor, and especially to its armature, described in 1891. Fig. 1 and Fig. 2 show the device. The former is principally used in the American patents, while the latter is given in the English patent of the same year. The novelty of the armature construction lies in a winding containing closed sub-circuits, and another point is that the closed circuits do not coincide in number with the poles of the field magnet. Before going into the action of this device, I will mention two simple experiments which are essential in order to understand the operation of this rotary magnetic field system.

If we have a closed coil moving in an alternating magnetic field, or better, between the poles of a field magnet as illustrated in Figs. 3 and 3A, energised by alternating

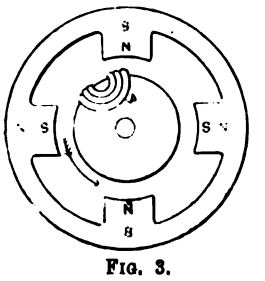

FIG. 3.

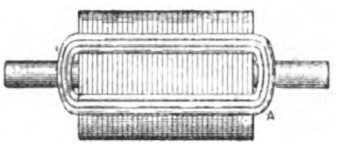

FIG. 3A.

currents; then the coil, A, will be repelled from the pole, owing to the secondary field which it establishes, so long as it cuts or is threaded by the lines of force of the field. The consequence is that it will rotate, and place itself between the north and south pole, Fig. 4, where it reaches a stable magnetic equilibrium, as I like to term it, because in this position it acts like a pendulum properly suspended, Fig. 5. Any motion imparted causes the pendulum to make a few oscillations and come to rest, and similarly any attempt made to move the coil into an energised field will cause it to be repelled, and after a few oscillations it will remain at rest between the poles. It is repelled in either direction, because as soon as it approaches a strong magnetic flux currents are induced in its windings and create an opposing field. The same coil can be in unstable magnetic equilibrium, Fig. 6, if it stands just in front of a pole, in which position it would act like a pendulum which is balanced with the weight above the point of support, Fig. 7.

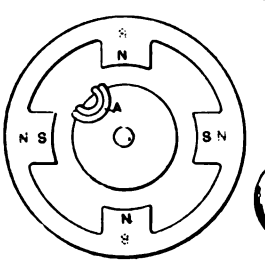

FIG. 4.

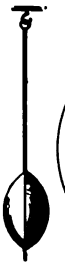

FIG. 5.

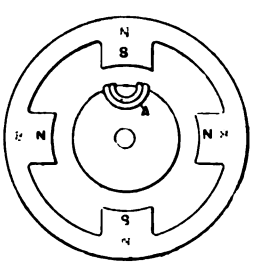

FIG. 6.

FIG. 7.

Both are in unstable equilibrium. The least motion to the left or right imparted to either will cause them to accelerate in the direction of the impulse, and to assume a position of stability, Figs. 4 and 5. In this position, Fig. 4, the coil is therefore currentless. This stable position is the natural position of synchronous motors in operation.

If such a synchronous motor is held behind the phase when rotating under load, a heavier current is induced in the spools which accelerate the armature and keep it in step. If, however, the motor runs in harmony, and suddenly a great deal of the load is taken off, then the armature has a tendency to go more quickly, but in this case opposing currents are generated in the windings which retard the speed of the armature and keep it back, to remain in step, or in stability.

Let us look into the device before us, and consider first its quality as a motor. Returning to Figs. 1 or 2, preferably the latter, which is simpler and easier to explain, we find that if we send into the field-magnet coil an alternating current, the armature will turn through a certain angle and stop. This motion depends upon the position of the three closed coils with respect to the two poles. This same device can itself be self-starting if we make the poles far enough apart and the energising current sufficiently strong, so that at the initial speed the armature is repelled at a certain rate. This initial speed changes with the number of poles, closed circuits, and alternations. Let us take the first case and examine it. If we try to rotate the armature (as I shall call it hereafter) in a field of alternating polarity, we induce currents in the closed circuits which establish poles, but these poles are alternating in

* Silvanus P. Thompson, 'Dynamo-Electric Machinery,' fourth edition, page 186."

† Paper read before the American Institute of Electrical Engineers.

Digitized by Google

nature, and owing to the motion imparted, and owing, further, to the permanent connections in the winding, the poles move or travel with the latter. This accounts for the fact that if the field poles are close together the armature consumes power during its rotation through the alternating field; it acts as a dynamo, and does not start from a state of rest. If we impart by mechanical means an impulse to the armature, currents are generated whose sum has a variable and principally negative value. The armature makes a few revolutions and places itself in a stable magnetic equilibrium—viz., in such a position, symmetrical if possible, as not to generate any currents, and hence not to induce any reactionary* poles in the core. If, however, we impart to this armature a certain initial speed, which I shall call the critical speed, then it will continue to rotate, with a tendency to reach a certain fixed higher speed. This initial impulse may be given by

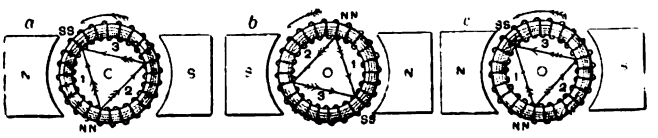

FIG. 8.

mechanical or electrical means. I shall not state the results as yet, but prefer to explore the action first, so that the same may be before us in various diagrams, and enable us to make any deduction desirable. First, let us assume that the armature rotates synchronously: it is evident that in order to have an armature with three close-circuited coils, interconnected as shown, rotate in one direction, we must have currents induced whose sum has a positive value—viz., two of the coils must do work, in the same sense, while the third coil is either without a current, or has a smaller current in opposite direction, so that the value still remains positive. For true synchronism, a close-circuited coil reaches within a half-period the opposite pole, and consequently our diagram for one revolution would look as follows (see Fig. 8).

The three diagrams, *a*, *b*, *c*, show the flow of currents and resultant poles. The close-circuited coil 2, diagram *a*, is at this moment generating opposing currents to the others; coil 1 is passing just in a front of a pole. All three induced currents combined are developing poles, as indicated, and rotating the armature in counter clockwise direction. The rotation being synchronous, diagram *b* shows the position of the armature when the polarity in the field has reversed; diagram *c* gives the position of the coils after the polarity has changed again. It will be noticed that the original position, as shown at *a*, has been reached again, and that the cycle will repeat itself. Without explaining these diagrams at this point, I wish to bring before you several other conditions, all of which will assist in reaching definite conclusions. Looking at the armature, we see that it has a symmetrical winding, and as long as these closed circuits do not coincide with the number of poles of the field magnet (contrary to all synchronous motors built heretofore), other working positions are possible. The operation will take place as long as the sum of the armature currents have a positive value,

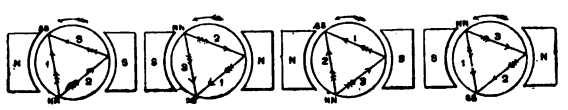

FIG. 9.

since as far as the rotation is concerned it is indifferent which of the coils are doing the work. Let us assume that the armature does not run at a synchronous rate, but at another fixed speed which may have a certain commensurable relation to the periods of the exciting field current, which speed I shall call the harmonic speed. Instead of showing the diagram with windings as in the first set, I have simplified them. In the following sets of diagrams, Fig. 9, I assume that the armature, on account of the load or other reasons, cannot reach synchronism, and that at each field reversal the position of the armature with respect to the field is the same, only the coils have changed places as indicated. You will notice that in this set of diagrams the armature, for each half period, makes one-third of a revolution only—namely, coils 1, 3, and 2 exchange positions with the change of polarity. Let us step at once to another speed, Fig. 10, which you will no doubt admit as possible—viz., let us assume that coils 1, 2, and 3 cannot arrive at synchronous speed, and that coil 2 reaches the position which 1 ought to occupy; it will be seen that, owing to the symmetrical position, it is quite indifferent which of these coils arrives at a given position required for harmonic operation. This will be clear to you by referring to the third set of diagrams, Fig. 10.

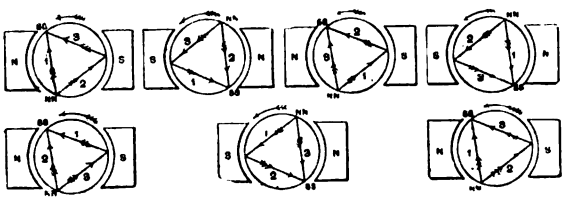

FIG. 10.

We are now enabled to compare three sets of diagrams, Figs. 8, 9, 10. The first set shows for this new type of synchronous motor that at synchronous speed the pole positions in the armature are practically stationary relatively to the coils and core and rotate with it. The second set shows that during a complete revolution of the armature the field has reversed three times—that is, an odd number of times—hence when the armature returns to its original position after a complete revolution, it finds the field magnetisation of reversed polarity. The magnetic field of the armature rotates in the opposite sense, one and a half times per revolution. In the third set, the armature makes but one-sixth of a revolution per half period, and the magnetic field of the armature in a complete revolution rotates three times in the opposite direction. This statement may be startling, and my argument, so far, may not be entirely convincing, as on close inspection it will be found that the armature poles have to do considerable jumping. I will now explain the performance of the rotary magnetic field of this armature in a four-pole field, where the changes occur far more gradually, leaving no doubt whatever as to the assertion made. Fig. 11 shows diagrams illustrating synchronous speed. By the aid of these four diagrams we can more easily follow the pole positions in the armature core, and find them stationary in it. Inspecting now Fig. 12, in which the armature speed is reduced, we are able to obtain a clear picture of the main subject under consideration.

FIG. 11.

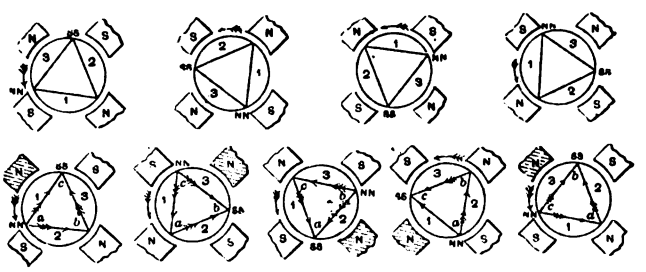

FIG. 12.

In this set of five diagrams we see five positions, which coil 1, for instance, occupies before it has made one-third of a revolution. Nevertheless, if we now look at the changing pole positions we can readily detect that they are progressively shifting, and we also see that they have made one whole revolution, and that in opposite direction to the mechanical rotation, or, in other words, the magnetic field would travel three time around the armature core during one revolution. In all armature diagrams described and to be described, the resultant of the magneto-motive forces of the armature currents is given only. To complete the picture showing everyone of the component magneto-motive forces acting, it becomes desirable to plot a diagram

* It is well to call the armature poles due to the armature currents, reactionary poles. The other armature poles are induced directly by the field poles, and contribute nothing to the torque.

Digitized by Google

of force, Fig. 13. These components act like three variable concurrent forces, including an angle of 120deg. with each other. These forces we may represent as equal for the sake of convenience, as it does not influence the idea which we wish to illustrate. However, those two forces which are acting in the same direction are indicated by heavier lines.

Plotting the direction of the forces in order, as, for instance, in the last-named set of diagrams, Fig. 12, where the coils act in the order 1, 2, against 3; 3, 1, against 2; and 2, 3, against 1, we obtain Fig. 13 for one cycle. The three figures marked *a*, *b*, and *c* indicate the direction in which the three forces are acting in the three positions of one cycle or revolution. By drawing the resultant diagram of force from the predominating forces of each position, we obtain the accompanying figure, Fig. 14. These forces form a triangle, and the rotation resulting may be seen from the direction of arrows on the circumference of the surrounding circle. However, the reactive forces should be considered and represented separately to obtain the true picture, and we have to add them to find the total force applied and the manner in which all the forces are acting. We, therefore, repeat the resultant diagram, Fig. 14, and add the opposing forces at their proper places. This diagram, Fig. 15, shows that the reactive forces, shown by dotted arrows, also have a common centre, and that as regards time of maximum effect, they succeed each other in the direction of rotation of the armature, while they are acting in the opposite direction of the main force. If we now plot a diagram of these reactive forces alone, we obtain the smaller triangle shown, Fig. 15, inside the larger. It will be noticed that rotation is in the opposite direction, or, in other words, that in reality we have, with this disposition, to deal with two rotary magnetic fields in opposite direction; the useful work done will depend on the difference of the angular velocity of these two rotating fields and their relative intensity.

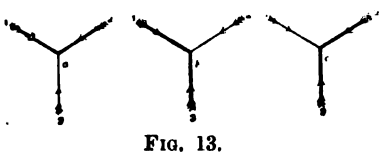

FIG. 13.

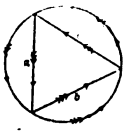

FIG. 14.

Looking now at the device as a generator, Fig. 12, we can account for the rotary magnetic field because we generate polyphased currents in the coils 1, 2, and 3. They operate together in the following order: 1, 2; 3, 1; 2, 3; 1, 2, etc. If rotated as shown, the coils will distribute three-phased currents over the armature, and this will be understood when examining into the flow of currents of the close-circuiting conductors which are here provided with arrows. At this particular harmonic speed it will be further noticed that the simple alternating field of force has the identical qualities as a polyphase energising field, as the poles in front of the close-circuited coil seem to be travelling (for the armature) in clockwise direction. This is indicated by the shading of the pole of same sign in front of the coil most powerfully acted upon in the five positions, representing one revolution for the field. The currents displaced in phase cause the armature to rotate harmoniously with the alternations, and prevent the armature from being easily thrown out of step.

Returning once more to the earlier diagrams, Figs. 9 and 10, we see that below synchronism there are two other speeds which are entitled to be called synchronous, because a certain fixed relation exists between the periods of field excitation and armature rotation. It will be evident that the greater the number of closed circuits, the greater is the number of harmonic or synchronous speeds in which the armature can operate. If the armature contains 10 closed circuits, and rotates in a two-pole field, it will be able to generate five currents, lagging 72deg. behind one another in phase, and would have at least five speeds which are synchronous, and the armature, owing to its peculiar construction, can operate at a slower speed than the synchronous speed as interpreted heretofore.

Looking at the device from a general standpoint, it will be clear that this particular armature construction embodies all the weak points of a synchronous and all the strong points of the polyphase motor. The weak points are: (1) That the machine will not start from state of rest in the form shown, because in Figs. 1, 2, and 12 the coils act on one another differentially, and have a variable and negative value; they are in magnetic stability when at rest, hence no rotation can result. (2) The device has a small starting torque when rotated, owing to the differential action of the coils, which cause, with a small number of closed circuits, strongly oscillating or jumping poles until a harmonic speed is reached. (3) The device when in rotation is not reversible by simply changing circuit connections.

The strong points are: first, that the motor develops polyphased currents in its own windings; second, that therefore it is more difficult to pull it out of step as it has the capacity to stand what I would term magnetic slippage.

Let us assume that a certain coil, which should reach a given point to run harmonically, remains behind owing to a slower motion of the armature; in this event the coil ahead has to perform the function at the expense of a slightly heavier current. The loss of revolutions due to this action may be comparable to the slipping of a belt over a pulley. However, there is also a limit to the slipping. The armature should have some harmonic speed with respect to the alternations. Should it fall below the lowest harmonic speed, then it will come to a standstill just like any other overworked synchronous machine.

Synchronism in a motor means nothing more or less than a magnetic flexible clutch, which may be represented mechanically as follows: The old fashioned non-starting synchronous machine having equal armature coils and field poles, can be compared with the arrangement shown in Fig. 15A, giving side view and elevation. The disc 1 is provided with two projections; 2, imparts rotation to shaft 4 by means of the flexible arm, or spring 3, which

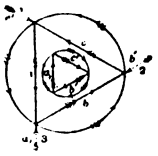

FIG 15.

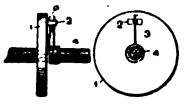

FIG. 15A.

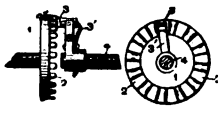

FIG. 15B.

enables the shaft 4 to be slightly behind or ahead of disc 1. However, if the work put on shaft 4 is in excess of the strength of spring 3, then it will break, and shaft 4 will speedily come to a standstill.

In contrast to this older form of synchronous motors stands the new one, which forms the subject of this paper, and the machines operated by bi- or polyphased currents. The mechanism for showing magnetic coupling for these latter types may be represented by Fig. 15B. In this case, 1 represents a crown wheel, the teeth marked 2; into these teeth meshes a catch, 3, in a flexible manner, which catch is connected rigidly to shaft 4. Within the range of normal work catch 3 would remain fixed between the two given teeth, but if the shaft 4 is overloaded, the flexibility of catch 3 will cause it to yield and pull out of its position, drop in between some other two teeth, and continue to operate, but at a slower speed. The greater the excess of work the greater will be the slippage, and the more teeth will be jumped by the catch 3 in every revolution of disc 1. For the synchronous motor herein described, the overloading to the extent that it cannot reach the lowest harmonic speed, would be equivalent to the breaking of spring 3.

It will be remembered that Prof. Ferraris always, and Tesla sometimes, obtained a rotary magnetic field and rotation by influencing one coil carrying a primary current, by another at right angles thereto carrying secondary currents. Here we have two phases from a single source, Fig. 16. To obtain a multiple of phases we may take two or three iron cores, A, and surround them with coils, B, like the links of a chain, Fig. 17, so that the secondary coil of transformer 1 is the primary of transformer 2, and so on; or we may design a special core for a transformer, and create a rotary magnetic field by applying to one coil

Digitized by Google

a primary current from the line, and to another coil a secondary current from a transformer, whereupon, by the rotary field obtained, polyphased currents may be taken through other coils on the transformer. These methods have, however, one drawback, and that is that the phase will change more or less in lag with difference in load, while, for many purposes, it is most essential that for efficient working the phase should remain at the same constant angle. This desideratum has been accomplished by the device under consideration, and any suitable number of currents lagging in phase may be obtained from a single alternating current.

To obtain a rotary magnetic field in or by a stationary body, at least two electric or electromagnetic forces of definite phase relations acting at an angle to one another and changing at periods harmoniously are essential requirements.

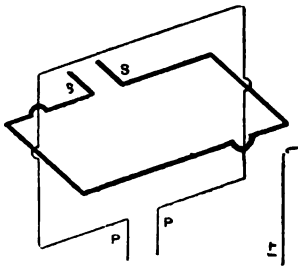

FIG. 16.

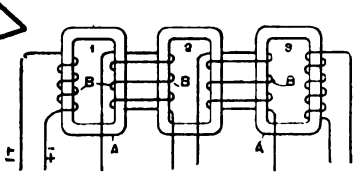

FIG. 17.

If, however, we allow the body, or part of the same, to be movable, we may substitute mechanical rotation primarily as an adjuster of the periodicity and phase of one of the two forces. The fundamental relation between the two forces must in this case also be the same as in the other—namely, they must work in harmony—and the periodicity and phase determines the periodicity and phase of the other of one force. If the second force is a current, it must be one of the same period or some harmonic of that period; if it is rotation, it has also to be synchronous or harmonic. We can now clearly understand why, when rotating the armature, Figs. 1 and 2, in an ordinary alternating-current field we have no system of polyphased currents and no rotary field, simply because the armature rotation does not stand in any relationship whatever to the alternations; but as soon as the speed does so, there are generated polyphased currents lagging in phase at a field angle, and a rotary magnetic field.

There is a difference whether the armature is influenced by a single alternating current, or by several, causing themselves a rotating energising field. Nevertheless, in either condition the armature is in magnetic stability, and this state is the reason that it remains stationary in the first case, and that it rotates in the second. The reason that the motor starts in the second case is evidently because the inducing magnetic field is itself rotating in the stationary field-magnet core. As said before, it is considered necessary for the proper operation of the armature for giving maximum torque that, if placed in an alternating-current field of force, the armature rotation should have a definite relation to the alternations. Up to the publication of this device some three years ago, synchronous motors had as many armature coils as field coils, and hence to obtain the value of the synchronous speed, all that was necessary was to divide the alternations of the armature current, n, by the number of field poles, p, of the magnet employed. But if the number of armature coils are not the same as the field poles, then the speed may vary from this synchronous speed, and a modification is thought to be necessary. We would have to find the smallest common factor between field poles, p, and armature coils, p^1, with which we have to divide the number of alternations to obtain the value of the lowest synchronous speed while the conditions of slippage may allow for the lowest harmonic, the value $\frac{n}{pp^1}$.

It will now be clear that motors can be designed having any desired variation of speed, and have defined synchronous speeds or approach the indifferent relation. I wish it understood that I do not intend to treat the subject in all its details, and I am especially reluctant on the ground of having carried on but few experiments.

The few diagrams presented do not disclose many conditions of those possible. They show only one or two facts of conditions which frequently are of a complex nature. Evidently, the rotary magnetic fields in the device under consideration may have altogether different speeds from those shown in the diagrams; also, that the magnetic field may rotate with and ahead of the armature; and, lastly, the speed of rotation of the rotary field of the armature may be synchronous and opposite in direction to its rotation.

The device has been given in form of a diagram, and as it has been described as not self-starting, I wish now to state that it becomes self-starting as a series, a shunt, or an induction motor in a field of single phase or polyphased alternating currents. Fig. 18 represents one of the earliest forms which have since been simplified to a considerable

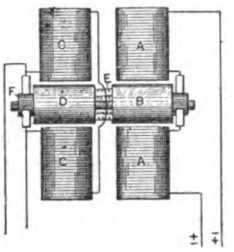

FIG. 18.

extent. The part A B represents here a simple series motor, whose armature, B, may be any Gramme or ring type, open or closed coil winding; the part C D may be similarly constructed. Both armature windings, B and D, are connected electrically by four wires, E, at points of equal distance, which number of conductors, E, may be reduced or increased, depending on the number of phase currents desired. Now send an alternating current into the series motor, part A B*, then the armature will start from state of rest and will send current impulses into the D part winding, which becomes the more regular the more the armature has approached synchronous speed, where bi-phase currents will be established therein; these react on the field-magnet core, C, and for the purpose of maintaining the armature in this synchronous speed, the commutator, F, is applied to rectify the polyphase currents, which continuous current may be used to energise the magnet, C.

The fundamental principle disclosed opens to us a very wide field for work. Not only are we enabled to construct motors almost as cheap and simple as continuous-current motors, but there is in this principle involved the germ for the ideal distribution of power, inasmuch as we are enabled to collect the polyphased currents generated, or commutate them immediately at will.

Finally, I wish to call your attention to the fact that the last figure is in reality a motor generator, and it is therefore evident that the electrical energy supplied need not all to be transformed into mechanical power, but that a portion may be utilised in one of the modified forms named above.

TRANSFORMER TESTING.†

BY EUSTACE OXLEY.

A transformer of the present day is an exceedingly efficient piece of apparatus, even when operated at small loads, but the combination of a large number of small transformers, with their primaries connected to the mains 24 hours out of 24, and with their secondaries open 18 hours or more out of 24, is a source of loss and inefficiency which has for a long time provided direct-current, low-pressure advocates with their main argument against the employment of the alternate-current system.

If consumers could be provided with a suitable switch for opening the primary circuit of their transformers when their lights were not in use, and at the same time could be relied upon to do so, this loss of power might be avoided;

* Preferably so that no reaction takes place from part D.

† *Electrical World* (New York).

Digitized by Google

otherwise, it would seem that the so-called "banking" of transformers, in connection with a low-pressure distributing network, was the only remedy.

In a system where every consumer is provided with a separate transformer, this loss at no load is of great importance in determining the all-day efficiency, and it is therefore advisable to test all transformers before they are sent out from the central station to be connected with the mains. Tests should be made of insulation, magnetising current, core loss, efficiency, and drop.

Insulation.—The insulation between the coils and between the coils and the shell should be able to withstand the application of P.D. equal to twice the primary voltage at which the transformer is intended to work; thus, a transformer intended for use on a 1,000-volt circuit should be tested for insulation between these parts, with a pressure of 2,000 volts.

Magnetising Current.—Measurement should be made of the magnetising current—*i.e.*, the current which passes through the primary coil when the secondary circuit is open.

Measurement of Core or No-Load Loss.—The "no load" loss is the power absorbed by the primary when the secondary circuit is open. There are several well-known methods of measuring the power taken up in a transformer, but they are not all, however, adapted for use in the workshop. Those commonly employed are the "three voltmeter" method of Prof. Ayrton and Dr. Sumpner; the "three-ammeter" method (a modification of the first by Prof. Fleming), and various "wattmeter" methods. The first two are very similar, the difference being that in one case you measure volts, and in the other current; in both a single instrument may be used to take the three readings. Eminent authorities have advocated the use of the wattmeter for measuring power in alternate-current circuits; however, workshops are seldom provided with a suitable wattmeter for the purpose. As the three-ammeter test can be made with an ordinary Siemens dynamometer and a voltmeter capable of measuring the volts on the low-pressure side of the transformers, it is perhaps most generally employed. Although this method has been frequently described, it is possible there are some who are not yet acquainted with it, so perhaps a short description would not be out of place.

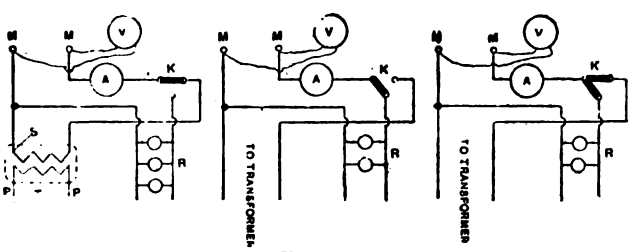

FIG. 1.

To measure the "no load" loss in a transformer, arrange things as shown in Fig. 1, where M M are the secondaries of another transformer providing the proper voltage, A the dynamometer, V the voltmeter, T the transformer under test, P the primary, and S the secondary coil; R is a non-inductive resistance, such as incandescent lamps; and K a three-point switch, conveniently made with mercury cups and copper connecting-pieces. The primary circuit is left open during the test. The voltage must be kept steady and at the proper value. Then if C is the current which flows through the transformers alone (when K is as in Fig. 1), and C_1 is the current which flows through the inductionless resistance, R, alone (when K is as in Fig. 2), and C_2 is the current which flows when the transformer and inductionless resistance are placed in parallel with one another (when K is as in Fig. 3), and V is the voltage, read by the voltmeter, then the power in watts absorbed by the transformer will be

$$W = \frac{V}{2\,C_1}\{C_2^2 - C^2 - C_1^2\},$$

the greatest accuracy being when C is made equal to C_1.

Efficiency Test.—When it is required to test the efficiency of a transformer at different loads, taking measurements on the low-pressure side, two similar transformers are needed. The primary coils of the two transformers are connected together, and measurements taken of the power taken up by the secondary of the first and that given out by the secondary of the second. The loss is then divided between the two transformers, and their efficiency determined. Dr. Sumpner has given a method for measuring the iron and copper losses in a transformer by means of a single wattmeter. It consists in measuring the watts taken up by the secondary when the primary circuit is open; this gives the "no load" or "core" loss, then the secondary is short-circuited, and the power measured absorbed by the primary when the full-load current is passing in the secondary. This gives the "copper" losses, and adding these two together gives the total losses in the transformer.

A method of finding the efficiency of good closed magnetic circuit transformers at all loads is to calculate the $C^2 R$ losses at different secondary loads, and adding to this the "core" loss, thus getting the total losses at different loads, from which an efficiency curve can be plotted. The "core loss," which is constant at all loads, may be got by multiplying the apparent power absorbed at no load by O S. This last figure is the value of the power factor at no load, as determined by Prof. Fleming after an exhaustive series of tests on transformers of different makers.

Regulation.—The drop in the volts of the secondary circuit with increase of load should be measured, the "total drop" being the difference between the secondary volts at no load and full load. This drop of voltage is due to resistance in the primary and secondary coils and to magnetic leakage. It is, of course, desirable that transformers for use on lighting circuits should have as small a drop as possible.

EXPLOSION IN EUSTON ROAD.

The daily papers have this week contained reports of an explosion which occurred a few minutes after midnight on Saturday, between Endsleigh-gardens and Gower-street, on the south side of Euston-road, whereby about 40 yards of pavement were displaced, and the cover of a large manhole, with several flagstones, was blown into the air. Two pedestrians who were passing at the time were injured and had to be conveyed to University College Hospital. They were there found to be suffering from the effects of a severe shock. An inspection of the scene of the disaster was made by the electrical experts of the St. Pancras Vestry. It is supposed that an escape of gas reached the electric wires which pass under the pavement and so caused the explosion.

Major Cardew has made an inspection, on behalf of the Board of Trade, of the scene of the explosion. Mr. Pycraft, chief clerk of the electricity department of the St. Pancras Vestry, stated, a few evenings ago, that nothing definite was yet known as to the cause of the explosion. He said it was curious that on January 12 last a similar accident took place in Endsleigh-gardens, about 100 yards from the spot where this explosion occurred. The officials do not think that the explosion could have been caused by sewer gas. That it was due to an accumulation of coal gas, however, they consider very probable. An inspector says that he reported an escape of gas in the immediate neighbourhood about a fortnight ago. The officials think, too, that the frost may have had something to do with the matter, two similar explosions having occurred during a frost last winter.

Mr. J. T. Baron, M.I.E.E., the chief engineer to the Vestry, informs us that within 20 minutes of the explosion he noticed a smell of coal gas on the spot.

Major Cardew, inspector of the Board of Trade, has written to the vestry clerk, stating that the Board will hold an enquiry into the matter. The enquiry is to be held at the Vestry Hall on Thursday next, commencing at 10 a.m.

Electric Lighting in Switzerland.—The local authorities of Altdorf propose to expend £2,000 on a central electric lighting station.

YEAR GONE—YEAR COME.

A HAPPY AND PROSPEROUS ONE TO ALL!

In that memorable prose epic, "The Pilgrim's Progress," John Bunyan has not given a particularly attractive character to Mr. Facingbothways, whose nature it was to metaphorically "sit on the fence"; yet in many respects this gentleman was a most estimable individual when he lived up to the literal significance of his name. He had a still more worthy ancestor called Janus, who reached the dignity of Roman godship, and rivalled the Siamese twins in the number of his heads. The latter, as most of us remember from our school days, were turned in opposite directions, so that their owner could look forwards and backwards at the same time: and the same kind of pastime is what we all try to indulge in at the opening of Janus's month—the opening, too, of our New Year, if not that of the Romans.

Whilst, however, it is good to emulate Bunyan's puppet in so far as his name is concerned at this particular season of the year, there is no occasion or need to speak with an uncertain voice, and "trim the sails to every favouring wind," when abstract principles and their practical application to electrical work come up for discussion, in the way that they are somewhat prone to do just now. Like Janus, we face both ways—we

> "Look back, look on: for midway now we stand
> 'Tween two sweet seasons—past, and that to come";

but it is only for the purpose of guiding the future by the failures of the past, of gauging possibilities, expectations, and hopes. It is well for healthy humanity in this respect that we live rather more in the future than in the past, and most of all in the present.

Looking backwards, what is there to criticise, to blame, or praise? The past year has been pre-eminently one of commonplace hard work, with the usual concomitants thereof—viz., some amount of profit, and a healthy feeling throughout the entire industry, just as in the individual a clear conscience and sound mind and body are promoted by the same means. No small thankfulness may be felt and expressed at the, comparatively speaking, pure air which electrical enterprise has breathed of late. The days of ill-starred and even fraudulent speculation have departed, it is to be hoped, for evermore, and the efforts of all are now directed towards legitimate trading and hard, steady work rather than loose gambling with worthless counters.

The abundance of work, even though not very remunerative except when large or numerous contracts are secured, has, however, brought into the field an enormous amount of competition, not merely between firms properly equipped and experienced, but also from those who cannot by any stretch of imagination lay claim to the title of "electrical engineer." Wherever central supply stations have been erected or even proposed by local authorities or private interests, there has at once sprung up a host of installation firms anxious to undertake wiring jobs at any price so long as they obtain the work, and are allowed to put up an elegantly

Digitized by Google

enamelled signboard stating that the "electric lighting is by John Smith and Co. *All work guaranteed.*" The nature of a guarantee is in such cases too often rather more dubious than the qualifications or ability of the advertiser to carry out the work in a proper fashion, but the customers who employ firms of this stamp are really not altogether to be pitied or even enlightened as to the expense and danger of giving a free hand in wiring their premises to the nearest sanitary engineer or registered plumber. If a firm allows itself to take up work of a highly skilled nature without the least qualification or special care, any guarantee of efficient results given to customers can hardly have much more value than the paper upon which it may be written. We do not, of course, emphasise this point from any jealousy of the new-comer; it is an excellent sign of healthy trade when plenty of competition exists, because it shows that there is a strong demand for electrical installations, so long as fair prices rule with good work. Undercutting by electrical firms properly so-called, in order to get mere numbers of jobs, cannot, however, be too strongly deprecated; whilst the entry of unqualified workers—the gas-fitter and bell-hanger whose ideas of a good joint are two wire ends twisted together, and who prefer staples to casing because they are cheaper—into the field of installation work affords even stronger ground for remonstrance.

The tendency of both these evil courses is to bring electric lighting most unfairly into disrepute: the work is scamped, bad material is used, and worse labour. The consequence is that breakdowns ensue, and the customer is put to endless expense in remedying matters. It might be thought that the day for jerry work had long passed by, that the fire insurance interests were by now sufficiently awake to the importance of care in accepting such risks, and that the supply companies or central-station authorities would also preclude by their compulsory tests the possibility of bad work. The greater competition grows, the more likely, however, is the danger to continue, and it is to be feared that there is even to-day as much tendency as ever towards want of common honesty in purpose and effort throughout installation work. Customers are too often tempted by low prices to pass over the firms of repute (of whom we are glad to say there are very many) and give orders to Tom, Dick, or Harry, who quote a figure perhaps twenty-five or thirty per cent. less in order to get the work at a loss, to be made up by the "extras" and commission here, there, and everywhere.

It is somewhat with a feeling of relief that one turns to the electrical manufacturing interests: these may be said to lie now in the hands of a few, perhaps not more than a score all told, but their products are sound and reliable throughout. A firm of any importance in the manufacture of electrical appliances depends essentially upon its own good name and repute: its apparatus is designed and built to give lasting satisfaction, and this good result has been secured in proportion as the chief part of such business has become concentrated in the hands of a few. This sentiment of working for permanent effects would benefit the electrical trade enormously were it also to permeate the smaller workers, so that every man engaged in it might feel that his humble share of the whole task, however small, could be no better done.

Just as the installation firms have found plenty to do during the past year in the branches and twigs of each electric supply tree, so also the large manufacturing interests have been busy in the trunks and roots—in equipping central stations throughout the country, either for local authorities or private interests. Hardly a week has passed by without the completion and formal opening of some electricity supply central station being chronicled in our pages: and no small importance is to be attached to the fact that the great majority of these have been carried out by municipalities themselves. No stronger proof could be offered of the absolute confidence now felt in the use of electric energy as a means of obtaining artificial illumination, when public bodies thus engage in its development not merely for the lighting of houses and other interiors, but also for their streets and roads—a far more serious matter, since the public service is thereby involved.

So far, our remarks have dealt more particularly with electric lighting progress, because, unfortunately, but little can be said as to any developments in the use of electric power. The past year has seen the equipment and opening of the Douglas and Laxey electric line, and the projection of others; but so long as tramway enterprises generally in this country stand on so "impossible"—to use a French expression—a basis, little progress can be expected in electric traction upon our streets. The various "special" lines — the underground electric systems projected in the Metropolis, the elevated lines, etc.—are no further forward to-day than they were at this time last year; and this also must be ascribed to financial causes rather than any conceivable defects or want of development in electric traction, just as its use on street tramways is lacking because of the ridiculous Tramways Act, and the prejudice amongst the ignorant against an overhead trolley wire.

Applications of electrical power in general are, it must be said, but little more numerous now than a year ago: isolated plants have been erected and are most successfully at work, whilst in a few places—as, for instance, at Manchester, where a continuous-current system is employed—there are scattered examples of power uses employing electric motors for such purposes as hoisting, packing, etc. The want of a really suitable alternating-current motor, which can be relied upon to work under similar conditions and with equal economy, is still very marked, though great advances have been made, and, thanks to the Oerlikon factories, at least something of the kind is now available.

The tendency throughout the past year in regard to the generating plant of an electric supply service has been very markedly to take advantage of all possible appliances or methods which afford greater economy in the cost of developing energy, and many notable improvements have been suggested and brought into actual use. Not the least important

Digitized by Google

of these includes better methods of using town refuse and cheap generator gas for effecting an economy in the cost of fuel—by no means a small item in the total expenses per unit generated: and it seems likely that still greater developments in this direction will be seen during the year now begun.

Taken as a whole, 1894 has been an "average" period: it has brought steady progress all round, if not the remarkable leaps and bounds characteristic of previous years, and not altogether to be desired in comparison, any more than the individual man will benefit physically from a "hunger and a feast" so much as a regular course of plain living. Some of the tangible results of the year, as evinced by the reports furnished to us from the principal firms engaged in the industry, may be gathered from the following paragraphs, wherein we abstract, as usual, a summary of work done and contracts carried out:

Bennett and Druce.

It is gratifying to learn that this Preston firm, notwithstanding an existence of only slightly over 12 months, have done a large amount of electrical work, especially in the North of England. The firm make a speciality of millwork, and much reliance seems to be placed upon them for installations of this nature. They found business fairly good, but report that prices have been low owing to the keen competition in the trade. During the 12 months they have installed about 4,700 lamps, with 20 arc lamps and 15 dynamos (one being a 78-kilowatt machine), three steam-engines, three gas-engines, and one battery of accumulators. About two-thirds of this number of lamps have been erected in mills. One of the characteristics of Messrs. Bennett and Druce is that they do none but the very best class of work.

Bolling and Lowe.

This firm report that in the iron, steel, and allied industries the past year opened with bright prospects, but that they only lasted for a short time, and then business lapsed into its former languid condition. There is a plethora of gold and silver in Europe, but it is in the less civilised parts of the world that development is most needed, but they have not sufficient reserves of their own to purchase from us for cash. Business is limited to the "necessity trade" that exists, for no other name can they give to the demand now ruling, which only represents the completion of work commenced, and the replacing of worn-out material. It must be evident that the continued deplorable depression in our agriculture greatly tends to diminish the home orders for the iron trade. In the United States the McKinley tariff has been amended, but it has hardly given any benefit to the English iron and steel trades. Our chance of business in the States is diminishing day by day on account of their cheapened means of production. There exists a feeling that when the war between China and Japan is over it will lead to a development of trade in these two countries, especially China. They believe this will be the case, but not for a considerable period. Our railways are owned by companies whose maximum charges of conveyance of passengers and goods are fixed by Acts of Parliament. Reductions in these rates, however much wanted, cannot be demanded as a right. They may be granted by courtesy of the respective companies. Under such conditions it can hardly be wondered at that we pay between 30 to 50 per cent. more than continental people, whose lines generally belong to the State. The light railways question has lately been taken up strongly in the Press, and is attracting great attention, but an early development of the project will be deferred, as the Board of Trade is prevented by its regulations from facilitating progress without reference to Parliament and consequent delay. Cheap road railways—£2,000 per mile—are more likely to meet urgent necessities, whereas light railways would in many respects, in the first instance, be more of a convenience than a commercial success. The fact that prices of iron and steel in 1894 have barely shown any variation in face of decreased exports must be taken as a most encouraging sign, and they can hardly believe that when a change does take place it will be other than an improvement.

Browett, Lindley, and Co., Limited.

Among the most important contracts carried out by this company during the past year may be mentioned the supply of nine engines and complete steam-piping for the Ealing electric lighting station; one 250-h.p. compound vertical engine for extension of Derby Corporation electric light station; one 100-h.p. engine for the Prescot station (the second extension with the company's engines); one 500-h.p. compound engine for extension of the Sheffield station; the whole of the engines (horizontal compound) for Southport electric lighting station; the engines for the Salford station, consisting of three pairs of horizontal side-by-side Corliss engines (200 h.p. each pair), with condensers; and engine for Aberystwyth station. Besides the above the company have been extremely busy in all departments, having made a great many engines for smaller installations, such as mills, collieries, and ships.

Brush Electrical Engineering Company, Limited.

The works of this important company, both in England and Vienna, have been fully occupied during the year, the contracts upon which they have been engaged including all classes of work in connection with electric lighting, both for private installations and central stations. The company report a very large increase, not only in the number of men employed in their works, but also in their outdoor contract department, where they have had large gangs continually employed both in putting down central-station work and in laying and extending mains in various towns. Extensions in central-station plant have been carried out at Huddersfield, Sheffield, Bournemouth, and Hastings, while central-station contracts at Hanley, Worcester, Lancaster, Leicester, and Coatbridge have been completed during the year. The company have supplied electrical plant for Bolton and the Great Northern Railway Company's station at Holloway, whilst the electric lighting of the Industrial Exhibition at Earl's Court last summer was also effected by plant of the company's manufacture. The company are at present engaged upon the Dover, Wandsworth, and St. Luke's town-lighting contracts, as well as upon the engines for the Clerkenwell station, and extensions at Bournemouth, Leicester, Worcester, Hanley, and other places. The orders received during the year include some of the above-mentioned town-lighting contracts, and, in addition, a complete installation at Malta, and the supply of plant for the London Exhibitions, Limited. Among the more important orders which have been completed in the way of isolated installations may be mentioned the lighting of Arundel Castle for the Duke of Norfolk;

Digitized by Google

Battenhall Mount, Worcester, the residence of the Hon. Percy Allsop; High Tree Mansion, Redhill, the property of Mr. M. Marcus; and The Grove, Harefield, belonging to Mr. George Webster. The company have now in hand a large arc lighting plant for the Leith Docks Commissioners, and the lighting of the public library and Town Hall, by means of dynamos and gas-engines, for the West Ham Corporation. With regards to contracts abroad, the company's works in Vienna have recently supplied direct-current plant for the central stations of Wolfsberg, Riod, Zara, Schönlinde, Kitzbühel, Sternberg, Ujhely, and Risenstein, in Austria-Hungary; whilst in France, Mordey-Victoria alternators have been installed in the towns of Montargis, Riez, and Voroppe. In Australia, the company's branches at Sydney, Melbourne, and Adelaide have carried out important works, including the supply of plant to the Broken Hill Proprietary Company and the Rockhampton Coal and Gas Company; the lighting of the Hotel Metropole, Sydney; of the Hobart Exhibition; and of the sugar mills in Queensland. Among other foreign orders may be cited the supply of generating plant for the lighting of the Dutch State Railway station at Flushing, alternating-current power-transmission plant for Switzerland, projectors for the De Beers Mines Company, and the extension of the town-lighting station at San Carlos do Pinhal, Brazil. One of the interesting features of the company's record during the year has been the entire lighting of the Hastings sea-front by a large number of Brush alternating-current arc lamps. The result of this undertaking, which is, we believe, unique in the annals of alternating-current lighting, has called forth expressions of warm approval from many qualified judges. The Brush-Vienna arc lamp has also been put on the market since a year ago, and the headway it has made has been of the most gratifying description. While this lamp is suitable for either direct or alternating currents, it has proved itself a peculiar success with the latter, and the company have been overwhelmed with orders for its supply both at home and abroad. The Brush-Vienna dynamos, which were just making for themselves a place in Great Britain 12 months ago, appear to have found much favour in the eyes of users of electricity, if an opinion may be formed from the numbers which the works have been called upon to construct. Lamp-holders, plain fittings, volt and ammeters, are now among the manufactures of the company, and it is anticipated that the high-class workmanship and moderate price that are characteristic of these goods will secure for them a large and increasing demand. The company have now taken the sale of their incandescent lamps into their own hands, and have just issued a new price-list giving a description of the various types which they manufacture. These lamps are articles of every-day use, and the Brush Company, with 10 years' experience at their back, and the best and latest machinery in their works, feel in a position to furnish a supply whose quality will command the confidence of the general public.

Clarke, Chapman, and Co., Limited.

Judging from the formidable list sent to us of installations put up during 1894 by Messrs. Clarke, Chapman, and Co., of Gateshead-on-Tyne, the company have had a large share of important electrical work both on ship and shore. This is a satisfactory fact, but it is even more interesting to learn that the prospect for the present year is much brighter than that obtaining 12 months ago, the company having in hand a considerably greater amount of work. Among the important ship installations carried out may be cited those on the steamships "Duffield," "Aco," "Fontabelle," "Maroa," "Carlisle City," and the "Duplex"; four for W. Dobson and Co., Walker-on-Tyne; three for Sir W. G. Armstrong, Mitchell, and Co.; one for R. Stephenson and Co., of Hebburn; the "Glenfarg"; one for Short Bros., of Sunderland; a dredger for W. Simons and Co., of Renfrew; the "Turkestan," "Amelia," "Nestor," "Ixion," "Tantallus," "Johannesburg," "Anglian," "Fort Salisbury," "Powerful" (temporary lighting), "Alleghany," "Merionethshire," "Cleopatra," etc. The principal installations on land include the house of Mr. Fred. J. Scott, North Shields; the colliery of the Crown Preserved Coal Company, Cardiff; the vicarage of the Rev. J. F. Anderson, Coldstream; shipyard of Short Bros., Sunderland; colliery of Earl of Durham; the iron-works of the Seaton Carew Company, West Hartlepool; and the works of Tilghman's Sand-Blast Company, Sheffield. Apart from these, electric cranes have been erected at the works of Swan and Hunter, at Wallsend, whilst special electric galvanising plants have been laid down at the works of Sir W. G. Armstrong, Mitchell, and Co., Elswick; the Naval Construction and Armaments Company, Barrow-in-Furness; Hanna, Donald, and Wilson, Paisley; Palmer's S. B. and Iron Company, Jarrow; and H. J. Waterston and Co., Sunderland. Leaving aside the above-mentioned, Messrs. Clarke, Chapman, and Co. have supplied some large generating plants and switchboards for Messrs. Swan and Hunter, Wallsend, and a number of combined engines and dynamos and belt-driven dynamos for installations not carried out by them, as well as a number of search-light projectors of various types, etc. Amongst other important installations at present in hand may be mentioned H.M.S. "Powerful," "Juno," and "Doris."

S. Z. de Ferranti, Limited.

The volume of business transacted by this company during 1894 was a distinct improvement on the previous year. The trade in continuous-current meters has remained steady, and the company now number on their books the whole of the direct-current supply stations in England, the demand for meters during December being particularly brisk. The company have also been engaged in developing their alternating-current meter, which has lately been adopted by several supply stations, owing to the extreme accuracy and power of starting even with large-size meters with an 8 c.p. lamp. The supply of the whole of the electrical apparatus for the Portsmouth electricity station was also entrusted to the company, and included the provision of two 212-kilowatt slow-speed direct-coupled alternators, being the first of this type of plant erected in England, and a number of converters of the change-over and of the automatic type, the main and supplementary switchboards and the whole of the arc lighting plant being operated by their system of motor commutators. The company have supplied during the year a number of high-pressure dynamos, including two of 120 kilowatts, each direct coupled, for the central station at Caen; a 212-kilowatt extension plant for Portsmouth; a 300-kilowatt extension plant for Sheffield; and further dynamos for the British Insulated Wire Company, etc. Among the dynamos now on hand are the Edinburgh machines and a 100-kilowatt direct-coupled slow-speed dynamo for Islington. The company's system of running arc lamps by rectified current has proved a great

Digitized by Google

success, and plants of this type are now running at Cardiff and Portsmouth, and are on order for Blackpool, Prescot, Tunbridge Wells, and Islington, and Edinburgh, and several important contracts for this apparatus are on the point of being concluded. The company have also supplied the high-pressure switchboard for Salford, and have now a similar one in hand for Edinburgh. The company have good orders on hand to keep them going for some time, and there is every indication of this year being one of the busiest they have had.

Dorman and Smith.

Extremely busy during the year is the keynote of the report of this Salford and London firm. The supply of main switchboards for central-station and isolated plants has so largely increased as to necessitate an immediate extension of the factory where this class of work is turned out. As a result, an extra three-storeyed annexe is being designed. Most of this class of work is made for contractors who supply the generating machinery, since the firm do not undertake any branch of actual erection. A considerable increase has taken place in the output of the cheaper and stronger patterns of such fittings as brackets and pendants, pointing to a great extension of the use of electric light in industrial premises, where its introduction is more an economical necessity than a domestic luxury. While the demand for smaller accessories, such as porcelain switches, holders, etc., which are a speciality with the firm, has steadily increased in London, it has been much more marked in the provinces, and more so still in the colonies and abroad. Some of the largest consignments with which Messrs. Dorman and Smith have had to deal are for erection in India, China, Japan, Russia, the Cape, and Australia, clearly showing that electric light and power are coming more prominently forward. Although there has been a steady fall in the prices obtainable, this is more due, the firm believe, to a natural increase in the facilities for production than to unhealthy competition. On the whole, Messrs. Dorman and Smith contemplate the prospects for the new year with complete satisfaction.

Doulton and Co.

In addition to their usual large business in insulators for telegraph and telephone, battery jars, and the numerous applications of pottery to electrical purposes, this company have during the year executed several important contracts for the supply of their stoneware conduit for underground electric light mains. Among these may be mentioned Edinburgh and Sunderland. The former scheme is being carried out on an extensive scale, upwards of 15 miles of conduit having been laid. The system has also been used at Chelmsford, Preston, Brighouse, Liverpool, Manchester, and by several of the London supply companies, in all upwards of 140,000 yards of "ways" having been laid. Although of comparatively recent introduction, the Doulton conduit may be regarded as one of the standard systems available to engineers. Messrs. Doulton have during 1894 supplied most of the insulators required for underground bare copper mains throughout the kingdom, and they have special facilities for expeditiously turning out large quantities of these insulators. They have also furnished the insulators for one of the important electric traction schemes in this country. Another distinct branch of this firm's business is the erection of plant for the purification and softening of water. Their process has been extensively adopted for steam-boilers, and also for manufacturing purposes where the use of impure or hard water would be attended with disadvantage. They now have in hand plant of this description for the St. Pancras electricity works.

The Electrical Company, Limited.

It is interesting to record that, notwithstanding the generally reported depression in trade, this company announce having had a very successful year. Since the promising aspect opened in November, 1893, in the incandescent lamp trade this branch has assumed unexpected proportions during the present year. The extensive stock kept and the ability of the company to supply large quantities of lamps on receipt of order have no doubt contributed to this result, and the names, the company state, of most of the largest buyers of incandescent lamps, including her Majesty's Government, may be found on their books. The high standard of quality, life, and efficiency of the lamps has been maintained throughout, and in many cases unsolicited testimonials have been received. The company's lamps are at present, as the "E. C." lamps, familiarly known throughout the country. The sale of arc lamps has almost doubled during the year, and the "Luna" type of lamp, both for direct and alternating current, has earned a high reputation. These lamps are in use in some of the largest installations both in London and the country, including her Majesty's Government, and the company state that there are few central-station circuits to which they are not already connected. A new differential alternating-current lamp with constant focus is now being brought out, and it is expected that this lamp, in connection with the well-known choking coils, will materially assist in making alternating arc lamp lighting a success, and particularly for indoor and shop lighting. It gives a very equally distributed light, the upward rays being reflected from the ceiling much in the same manner as in the case of inverted arc lamps. A new and separate automatic cut-in and cut-out arrangement has been added for high-pressure series installations. This method fulfils all requirements that may be expected from such an apparatus, which will be a valuable acquisition in all high-pressure installations. The sale of the company's well-known type of lamp-holder has steadily increased until it has reached more than three times the quantity of last year, this being due to a steadily maintained quality and to a well replenished stock. The latest patterns are stocked. In regard to the Dolivo measuring instruments, which are also well known, it is noteworthy that their proverbial accuracy, combined with a low price, have induced a ready and still increasing sale. The insulating material "stabilit" is coming more and more to the front. Some of the most prominent firms have testified to having been highly satisfied with all the qualities of this material, particularly that of high insulation, even under the most unfavourable circumstances. For high-pressure work this material is claimed to be the *sine quâ non* of all insulating materials. During the year the company have added a new department. This is for dealing with the electrical transmission of power and light on the three-phase system, of which the company's main factory, the Allgemeine Elektricitäts-Gesellschaft, of Berlin, have made a speciality for the last four or five years, with highly satisfactory results. By means of this system, distance no longer plays that important part as it does in transmission of power by direct current. By means of this system electrical energy can be transmitted from the same

Digitized by Google

plant, both for simultaneous lighting and power purposes, motors being used which can start under full load, can easily be reversed, and having no commutators, sparking is impossible. These motors are therefore (besides being used for all ordinary purposes) particularly adapted for work in coal mines, where the ordinary motor with commutator and its inherent sparking is not advisable, and even dangerous. Although this department has only been started a short time, a number of important orders and enquiries to the extent of 8,000 h.p. are already in hand, and as a very considerable saving over any other known method of transmission of power can be obtained, the company consider it is impossible to see to what extent this branch will develop even in the near future.

Ernest Scott and Mountain, Limited.

This well-known Newcastle firm report considerable progress in all their departments during the past year. In the engineering department they have been busy with their specialities, and have supplied, or have on order, the main feed, auxiliary feed, fire, and bilge pumps for the following warships: H.M.S. "Ardent," "Boxer," "Bruiser," "Charger," "Dasher," "Hasty," "Handy," "Hart," "Hunter," "Hardy," "Haughty," "Janus," "Lightning," and "Porcupine," and also for the "Venus" and "Diana," second-class cruisers of the Talbot type. These pumps are of the duplex type specially designed to meet Admiralty requirements. The company have also in hand for the Ganges two large sets of stern-wheel machinery for two stern-wheelers being built by their agents in Calcutta. With regard to electric transmission of power, the firm have also been exceedingly busy, and have completed some important contracts of this description. These include electric pumping plant for the Lothian Coal Company, Dalkeith, N.B., capable of delivering 400 gallons of water per minute against a head of 700ft. For the Cambois Colliery of the Cowpen Coal Company, Blyth, they have completed pumping plant, replacing the old wire-rope pumping plant. This plant has been so successful that the owners estimate that the saving will not be less than £1,000 per annum. Complete electric pumping plant has also been supplied to Messrs. Strakers and Love for their Willington Colliery, co. Durham. This plant, which is worked from the waste heat from the coke ovens, costs practically nothing for fuel, and it is a new example of the economical way in which electric transmission can be utilised where fuel of this description is available Pumping plants have also been furnished by the firm to South Africa for the goldfields, and to collieries. The new type of electric coal-cutting machine introduced by the firm at the Glenclelland Colliery, near Wishaw, has also been equally successful. The cutter which is at work is daily cutting on a long wall-face 95 to 100 yards in 4½ hours 3ft. deep, and as the coal-cutter can be worked by two men it will be seen that for low seams mechanical coal-cutting of this description must replace hand labour where it is so expensive to work the thin seams. The success of this machine has been so marked that the company have in hand orders for four complete plants of coal-cutting machinery, whilst negotiations are proceeding for other plants. In the electric lighting department the company have turned out a greater number of dynamos than they have ever previously done, the machines all being of large size. In the early part of the year they completed an order for the English War Office for 13 dynamos to be combined with engines, and they have now in hand for the War Office a further order for 11 dynamos of the same type. A number of important installations has been carried out, including New Craig House, Edinburgh, this installation consisting of two boilers, four compound engines, four dynamos each capable of running 400 incandescent lamps, and about 1,400 lamps installed throughout the asylum. This is probably one of the largest and most complete installations in the world. Combined engines and dynamos have also been furnished by the firm for the Japanese cruiser "Yoshino" and for the Chilian cruiser "Blanco Encalada" the firm's improved type of central-valve engine being used for the latter vessel. The firm have carried out several important installations in private mansions, including the lighting of Dr. Tomlinson's house, Kirkby Lonsdale, and of the residence of Mr. Walter Wilson, Enfield, Gateshead. Contracts have been completed or are in hand for abroad, the most important being the lighting of the Ganges Jute Mill, consisting of two dynamos to run 800 lamps, and a rice mill in Cochin China. Two complete installations have also been supplied for mill-lighting in Russia, and Messrs. Jonas Brook and Bros.' new mill at Meltham, Huddersfield, has been fitted with a complete installation. Amongst local contracts for electric lighting may be mentioned installations for the Seaton Delaval Coal Company's New Hartley Colliery; the Garesfield Colliery of Messrs. W. Benson and Sons; the Derwent Flour Mills, Shotley Bridge; and Messrs. J. L. Thompson and Sons, Sunderland, new joiners' shop. A new departure is being made in the lighting of this shop by the adoption of arc lamps. This firm are also proposing to use the available power for working deck planers and other machinery of this description by electricity. During the year the firm have found it necessary to extend their works on account of the largely increased trade, and they have introduced electric transmission throughout. The old engines and boilers have been removed, and compound engines and boilers substituted, driving on to dynamos which feed the electric motors in the works. It is estimated that, notwithstanding that the size of the works has been nearly doubled, a saving of not less than £700 per annum will be effected. The new year opens with a larger amount of work in hand than the firm have ever had in any previous period.

Epstein Electric Accumulator Company, Limited.

This company report that their past year's business can be regarded as one of decided progress and success. After having given unexceptional results during the first years of probation, a large demand for Epstein accumulators could reasonably be expected, and these anticipations have been fully realised. Numerous batteries have been supplied for private installations, among others being for Lord Tollemache's seat at Peckforton Castle, through Messrs. Barclay and Son; and for Lord Houghton at Massingham, through the Planet Electrical Engineering Company; whilst regular orders from the Admiralty and the War Office prove that the batteries already erected give full satisfaction. Both the Cape and Natal Governments have again shipped large numbers of these cells, and most of the home railways have now Epstein accumulators in use. Many technical schools and public institutions the company state, prefer to lay down Epstein cells, as their robust constitution ensures long life, and for the same reason, in conjunction with the advantages of light weight and little space taken up, they are in large demand for electric launches, and in this direction a

Digitized by Google

considerable amount of business has been done. The company further state that the most pronounced evidence of the high favour in which this company's productions are held is, however, to be found in the fact that in several central stations the worn-out plates of other makes are being replaced by those of the Epstein Company, whilst the new batteries required for these, as well as for the central stations of the Wolverhampton and Lancaster Corporations, are entirely of the company's manufacture. The rapidly increasing demand for the Epstein cells has necessitated much larger works, and these have been secured at Milton, Staffordshire, where the entire staff of the London works has been transferred, the offices now being at 213-217, Gresham House, Old Broad-street, E.C. As a result of manufacture on a more extended scale the prices of the cells have been revised, and the new lists of the lighting types, affording considerable advantages all round, will be issued early this month. With regard to batteries for traction purposes, the developments and improvements made by Mr. Epstein in the manufacture of secondary cells for this purpose have been of such importance, the company say, as to remove the obstacles which have hitherto acted as a hindrance to their more general and successful adoption. Durability, compactness, high capacity, and extreme lightness (the weight being reduced to one-third of the present type, capacity for capacity) are combined so effectually in the new traction cell that this difficult problem may now in reality be claimed as solved, an achievement which, while greatly widening the scope for the application of accumulators, will not fail to exert a favourable influence on traction enterprise generally, and thus be instrumental in benefiting many industries interested in this branch of work.

J. K. Fahie and Son.

This Dublin firm have been busy during the year, especially in the capacity of consulting engineers. The firm has had several important proposals under consideration as regards the utilisation of water power for electrical purposes, and seeing the extent to which this natural motive force abounds in Ireland, it is to be hoped that ere long many examples of this kind of electrical work will be brought into operation. The junior member of the firm—Mr. Angelo Fahie—has been complimented during the year by being appointed by the Lord-Lieutenant of Ireland (Lord Houghton) to the Commission of the Peace for Dublin.

E. Green and Son, Limited.

It will almost be superfluous to say anything of Green's economiser made by this Manchester firm. Its merits as a means of increasing the economy in the boiler-house are well known, and our own columns have borne testimony of the high appreciation in which it is held by its adoption in many central electric light stations. The following list, which is convincive, shows the electricity works in which it has been adopted during the past year: Salford, Stafford, Reading, Halifax, Altrincham, Wolverhampton, Dewsbury, Coventry, Bournemouth, Dover, Great Yarmouth, St. Pancras, Bedford, Tunbridge Wells, Portsmouth, Lancaster, Holloway, Nottingham, Hampstead, Kingston, and the City of London Electric Light Company, Bankside. This is a good record, but this is enormously improved when the hundreds of economisers supplied to all classes of manufacturers are taken into consideration. The company consider there is a fair prospect of business during the present year.

J. H. Heathman.

The progress of electric lighting during the year just ended has caused an increased demand for and manufacture of Mr. Heathman's extension ladders, steps, and trestles. The telescopic trestles have been in good demand, whilst the extension tower ladders have been adopted for no less than 46 installations. The latest improvement is the elevating spindles, which Mr. Heathman now fits to his ladders for supporting the side that happens to be on the lowest ground, or over a road gutter, and so setting the ladder quite perpendicular. As to the saving of expense in recarboning arc lamps, the Great Northern Railway Company's electrical engineer states that the adoption of these ladders has enabled him to dispense with five men. Thus, the saving in the labour bill soon repays the purchase of the ladders. Mr. Heathman further reports that the prospects for the current year are full of hope.

Johnson and Phillips.

It is satisfactory to note that all the departments of this firm have been uniformly busy during the past year. As an illustration of this we may mention that the construction of alternators, dynamos, transformers, and central-station accessories has been more than double that of any previous year. One of the most important of the several large contracts upon which the firm have been engaged was for South Africa, being a polyphase electric transmission of power plant which is now being erected by the firm's representative at the mines. Another important contract was the installation for the lighting of the Waterloo Goods Station at Liverpool for the London and North-Western Railway, where complete plant was supplied for 36 arc lamps and over 700 incandescent lamps. This firm also obtained the contracts for the Bedford Corporation electricity works, and the steam alternators and arc lamps for Tunbridge Wells. The number of dynamos for various purposes built during the past year has been largely in excess of that of former years, and the number of transformers has almost doubled those made last year. The cable department has been very busy with the manufacture of high-class vulcanised cables for installation and underground work, for which the number of orders still continues to increase, and a large new shop has been added to this part of the works so as to enable the work to be turned out more rapidly. Large quantities of cable have been sent abroad, principally to Spain and South Africa. An important contract executed by this department was the laying of the high-pressure feeders on the Brooks insulated oil system for the Worcester Corporation. The activity manifested in the arc lamp department testifies to the popularity of the Brockie-Pell arc lamp, for which the large number of orders received shows that it still holds its own against all competitors. Amongst others, these lamps have been furnished during the last 12 months to the General Post Offices in London, Glasgow, and Hull; to the London and North-Western Railway, Liverpool; Great Northern Railway, King's Cross and Holloway; the Lancashire and Yorkshire Railway; and the Corporations of Wolverhampton, Ealing, Londonderry, Portsmouth, Nottingham, Birmingham, and Tunbridge Wells, whilst Mr. William Whiteley, of Westbourne-grove, is also very extensively using the Brockie-Pell lamps. In addition, a large number has been supplied for lighting the Blackpool Tower and buildings, and for many other important installations. The orders for carbons have been very large during the past 12 months, and greatly in

Digitized by Google

excess of previous years. The manufacture of the "D.P." accumulator has kept this particular department more than usually busy. Orders continue to come in steadily, showing that the advantages of the cell are being recognised as it becomes more widely known. The Perry meter, the manufacture of which has been taken up by the firm, has been greatly perfected, and this department is very active in executing orders for the latest permanent magnet type, which has proved most satisfactory in its working. On the whole, the progress made during the past year is highly satisfactory, and the firm consider that the outlook for the future is very gratifying.

Lithanode and General Electric Company, Limited.

This company, to whose admirable results in the direction of obtaining remarkable scenic effects on the stage we have occasionally referred, inform us that, owing to the success which has attended their efforts in former years in the production of novel electrical effects on the stage, they have during the past year had a great deal of work in hand. The contracts include not only work for the best theatres in London, but the company also have in hand work for several important places of amusement in the provinces. Among the towns where they are installing electrical work may be mentioned Edinburgh, Sheffield, Manchester, Birmingham, and Portsmouth. The company are inclined to think that this year they will eclipse, in point of magnitude at least, their endeavours in past years.

Meldrum Bros.

That more consideration is being given to the use of forced draught in central stations is shown by the fact that this Manchester firm have during the past year fitted their well-known furnaces at the electrical works in Bolton, Pontypool, Glasgow, Loughborough, Bootle, Blackburn, Belfast, and Dublin, whilst their adoption has been decided upon by the Town Councils of Newport (Mon.) and Stafford and by the Islington Vestry. These furnaces have been for some time past in use at the stations of the House-to-House Company, at West Brompton; the Electricity Supply Company for Spain, in Madrid; the City of London Electric Light Company; and various other stations. At Rochdale refuse disposal works the Meldrum furnace is fitted to seven boilers, house refuse being the fuel employed. The refuse is destroyed and disinfected in a novel form of combustion chamber, and the heat from the fires is utilised to raise steam in the boilers. Part of the steam thus raised is used in the production of electric light with satisfactory results, full particulars of which will probably be available shortly. Orders are already in hand for further work of this kind, and the firm state that there seems no room for doubt that their method is a distinct advance in the utilisation of town refuse as fuel for producing electric light. The convenience of this form of draught, as compared with unassisted chimney draught in central stations, the firm state, to be very great, even apart from the question of economy. The command of the steam supply is improved, as all the draught can at any moment be applied and the boilers worked to their fullest capacity during a sudden demand for steam, while the draught can be regulated with the same facility to suit a very slow fire. With respect to economy, Messrs. Meldrum Bros. say that the bars are practically indestructible, thus ensuring a saving, whilst small fuel, as well as anthracite, small coke, etc., can be burnt efficiently in the furnace.

Mosses and Mitchell.

This firm, who make a speciality of vulcanised fibre and articles made thereof, report that the past 12 months have been an all-round good year with them. Their trade in hard and flexible vulcanised fibre sheeting, tubes, and rods has been good, while their saddle staples have been in exceptionally large demand by electrical engineers.

The following is a complete list of applications for provisional orders deposited with the Board of Trade up to December 21, 1894, under the provisions of the Electric Lighting Acts, 1882 to 1890:

Title of Order and Description of Area.	Name of Promoters
Alderley Edge Electric Lighting Order. The Urban District of Alderley Edge.	The Urban District Council.
Bath Electric Lighting Order. The City of Bath.	City of Bath Electric Lighting and Engineering Company, Limited.
Bootle Corporation Electric Lighting Order. The Borough of Bootle.	The Corporation.
Brechin Electric Lighting Order. The Royal Burgh of Brechin.	Scottish House to House Electricity Company, Limited.
Carlisle Corporation Electric Lighting Order. The City and Municipal Borough of Carlisle.	The Corporation.
Leigh Urban Sanitary Authority Electric Lighting Order. The Urban Sanitary District of Leigh.	The Local Board.
Liverpool Electric Lighting Order Portions of the City of Liverpool and of the Local Government District of Toxteth Park.	Liverpool Electric Supply Company, Limited.
Llandudno Electric Lighting Order. The Urban Sanitary District of Llandudno.	The Urban District Council.
Luton Corporation Electric Lighting Order. The Borough of Luton.	The Corporation.
The County of London.	
Battersea Electric Lighting Order. The Parish of St. Mary, Battersea.	County of London and Brush Provincial Electric Lighting Company, Limited.
Newington Electric Lighting Order. The Parish of St Mary, Newington.	Ditto
Notting Hill Electric Lighting Order. A portion of the Parish of St. Mary Abbotts, Kensington.	Notting Hill Electric Lighting Company, Limited.
St. Olave's Electric Lighting Order. The District of the St. Olave's District Board of Works.	County of London and Brush Provincial Electric Lighting Company, Limited.
Strand District Electric Lighting Order. The District of the Strand District Board of Works.	Charing Cross and Strand Electricity Supply Corporation, Limited.
Margate Electric Lighting Order. The Municipal Borough of Margate.	Municipal Electric Light and Power Corporation, Limited.
Montrose Electric Lighting Order. The Royal Burgh of Montrose.	Scottish House to House Electricity Company, Limited.
Motherwell Electric Lighting Order. The Burgh of Motherwell.	The Commissioners of the Burgh.
New Windsor Corporation Electric Lighting Order. The Borough of New Windsor and the Eton Urban District.	The Corporation of New Windsor.
Pontypool Electric Lighting Order. The District of the Pontypool Local Government Board.	Pontypool Electric Light and Power Company, Limited.
Prescot, Huyton and Roby. Rainhill, Eccleston, and Whiston Electric Lighting Order. The District of the Prescot Local Board. The District of the Huyton and Roby Local Board. The Townships of Rainhill, Whiston, and Eccleston.	British Insulated Wire Company, Limited.
Radcliffe Electric Lighting Order. The Urban Sanitary District of Radcliffe.	The Urban District Council.
Salisbury Electric Lighting Order. The City of Salisbury.	Salisbury Electric Light and Supply Company, Limited.
Southampton Electric Lighting Order. The County Borough of Southampton	Southampton Electric Light and Power Company, Limited.
Stirling Electric Lighting Order. The Parliamentary Burgh of Stirling.	The Commissioners of the Burgh.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

BANHAM v. REDDAWAY.

SIR,—We regret to find that a serious error crept into the report which we sent you, and which we did not observe at the time.

The report says: "It appeared that several years ago the Lancashire Belt Company made a camel-hair belting for machinery, and called it Reddaway's camel-hair belting," etc. It should be: "It appeared that several years ago the Lancashire Belt Company made a camel-hair belting for machinery, and sold it as the Lancashire belting. Shortly afterwards the plaintiffs made a camel-hair belting for machinery, and called it Reddaway's camel-hair belting," etc.—Yours, etc.,

W. C. CHEW AND SONS AND HILDITCH.

10, Kennedy-street, Manchester, December 22, 1894.

[The report referred to was published on p. 758 in our last issue.—ED. *E. E.*]

THE CARBONNELLE MICROPHONE.

Telephone engineers have for a long time supposed that the microphone invented by Prof. Hughes, and a most important part of any telephone system, has but little value for long-distance working without the use of an induction coil, as first proposed by Edison: and the consequence is that practically all modern instruments used for inter urban or even urban telephone circuits are provided with induction coils, by means of which the transmission voltage is raised to a point capable of carrying a sufficient amount of current over the considerable resistance of the line circuit. The adoption of this method is of course due to the comparatively low resistance of the carbon microphone, whereby the changes of resistance set up in it, as compared with the whole resistance of line and instruments, is very small, and not enough to affect the receiver; hence the use of an induction coil or transformer at each end, and hence, also, the necessary employment of a battery for each instrument to operate the same.

M. Carbonnelle has devised a type of microphone which is based upon a very high resistance, this being normally 1,000 ohms. When the instrument is used for speaking the resistance rises to six or eight times that value, and thus represents a large proportion of the entire circuit resistance. According to *L'Industrie Electrique*, this plan effects a very great saving in more ways than one. To begin with, all the batteries are maintained at the central exchange, and none are required on the subscribers' premises. A magneto call is alone necessary for each subscriber, and the massing together of cells at the exchange enables their number to be much reduced. Thus three Leclanché cells are found to be amply sufficient for clear speech over short distances, and as in practice one set of cells is enough to work five subscribers' lines, there are only 1,800 cells necessary for an exchange of 3,000 subscribers. Usually six cells are employed in the French telephonic systems for each subscriber, or 18,000 cells for a similar exchange—10 times as many—and involving much more trouble and attention, because they are scattered all over the network instead of being concentrated at the exchange. For inter-urban speech five cells are quite sufficient to ensure clearness. For instance, the telephone system at Brussels uses an earth return. It has multiple switchboards of 200 subscribers each, but only one cell is employed per subscriber. With the high-resistance microphone, instead of induction-coil instruments, three cells each are enough for 32 communicating cords used in urban work, and five each for eight other cords kept for inter-urban service. This gives a total of 136 cells, or a saving of one-third over those required on the old plan.

A large number of advantages is claimed for the new method on the score of less waste in the cells employed, greater convenience and reliability of service, better results over long distances, and so forth: there is certainly some novelty in the device since it completely upsets ordinary ideas about successful telephone working conditions. At the same time there seems no objection to its use or introduction into systems otherwise equipped.

ELECTRICAL ENGINEERING IN NEW ZEALAND.

A large amount of work has recently been carried out by the New Zealand Engineering and Electrical Company, of Castle-street, Dunedin. Mr. R. H. Postlethwaite, one of the members of the company, writes to us that their contracts include the erection of a small central station in the town of Gore. The plant at present consists of semi-Cornish multitubular boiler, two horizontal high-pressure condensing engines connected to an independent condenser, and fitted with automatic relief valves to atmosphere. The feed water is drawn from a hot-well, and is pumped through copper coils in exhaust-pipe from engine to condenser. The engines run at 130 revolutions, the governors operating direct on the cut-off valve. The whole of this plant was built by the company. There are two shunt-wound two-pole generators of 14 units each, running at 560 revolutions. When heavy load is on, these are run in series on three-wire circuits, but as the load decreases by the use of two two-way switches one dynamo is cut out, and the other takes the load on a two-wire system, the two outside wires being in parallel, and the neutral acting as the return. The voltage is regulated in the ordinary way by altering the resistance of the shunt circuit. Pilot wires, led back from the network to Cardew voltmeters, enable a constant voltage of 112 volts to be kept on the network.

The street wiring is overhead, with bare wires arranged on oil insulators, the farthest lamp on the net being 60 chains. The net is fed by four sets of feeders of equal resistance, the longest being 35 chains. The town is lighted by two arc lamps taking 15 amperes run in series, and 32-c.p. incandescent lamps in the by-streets. These lamps are run off the network, and are controlled from the station by a magnetic switch devised by Mr. Postlethwaite. This is of great convenience, as the street lamps are only needed until midnight. To private consumers the net price is 18d. per unit, or 3s. 6d. per month per 16-c.p. lamp installed. The supply is being rapidly taken up by the inhabitants. The meters used are of the Thomson-Houston type. Besides having installed the electric light in numerous mills, both arc and incandescent lamps, the company are now erecting an over-compounded 14-unit dynamo on a private estate to take the place of a four-unit one erected by them two years ago. The owner was so satisfied with his experience of the convenience of electricity when produced by water power that he determined upon a large machine which will run day and night, and besides lighting his house will do all the cooking and heating, also providing power for the various machines upon the estate.

ECONOMY IN STEAM RAISING.*

BY T. F. MELDRUM.

To effect the combustion of fuel for steam-raising purposes some means of producing the draught must be resorted to, and the question is whether it is better to build a high shaft and keep a column of gas in it at a high temperature, or to provide some mechanical means of either inducing or forcing the requisite air through the fire. Chimney, or "natural draught," as it is commonly called, depends upon the difference in the specific gravity due to the difference in temperature between the column of hot gases in the shaft and a corresponding column of the external air, and consequently must vary to some extent with the state of the atmosphere, humid or bright weather altering the condition considerably, whilst everyone who has had to do with the generation of steam knows how materially the direction and velocity of the wind affect the fires when natural draught is depended upon. A strong wind blowing from the ashpit, for instance, will sometimes necessitate the continual rousing of the fires to the discomfort of the stoker, as well as entailing a great waste of fuel.

Suppose instead of relying upon the chimney for draught the ashpit is closed and the required air forced in either by means of a fan or steam-jet apparatus, the same effects will be produced so far—namely, a greater pressure of air under the bars than over the fire—the difference being that instead of atmospheric pressure under the grate, and something less than that over the fire, we have approximately atmospheric pressure over the fire and something more than that under the grate. Several advantages will follow: (1) We shall be entirely independent of both wind and weather. (2) The whole heat of combustion will be available down to the temperature of the entering fluid, or even considerably lower minus the power required to produce the draught. (3) There will be no loss of draught nor cooling of gases through leaky brickwork. (4) The blast can be so regulated that no cold air whatever need be drawn through the fire-doors when they are opened for cleaning or otherwise attending to the fire, so that the heating surfaces may be kept at a more uniform temperature, greatly to the advantage of both boiler and setting. (5) The fire-grate may be considerably reduced in area and the fire therefore concentrated, by which means the large excess of air over the theoretical quantity required for combustion may be very materially reduced with a resultant much higher temperature and a consequent greater proportionate evaporation, the transference of heat being in proportion to the difference in temperature between the heating and the heated bodies. (6) As a much greater force can be readily obtained than could be the case with natural draught, except by means of an enormous and very costly edifice, greater power may be developed from a given size of boiler, or, on the other hand, much that would otherwise be considered refuse may be used as fuel with considerable advantage.

Mechanical draught may be produced in various ways—a fan may be placed in the chimney, or the exhaust-pipe may be somewhat confined at the outlet and introduced into the funnel, thus inducing a current of air through the fire, as in the case of the familiar locomotive blast-pipe. With stationary boilers, however, no such waste of the exhaust steam would be permissible, and, consequently, more economical means have been adopted. Some 20 years ago, Körting's arrangement was somewhat extensively introduced into the North-Eastern District by Messrs. R. and W. Hawthorn, of Newcastle-on-Tyne. After this the Perret furnace was extensively introduced into this country by Messrs. Bryan Donkin and Co., of London. In the furnace a water-box is placed in the ashpit, special bars with deep fins are used which dip into the water, and air is supplied by a pressure fan usually run by a small supplementary engine, as otherwise the forced draught can only be used when the main engine is running. Mr. J. Holliday, A.M.I.C.E., in a paper on the economy of steam raising, with special reference to the Perret furnace (several of which he has under his charge at the works of Messrs. Guiness, in Dublin) stated that the difference in cost of evaporating 1,000 gallons of water between the natural-draught boilers burning coal at 11s. 6d. per ton and the forced-draught boilers burning coke breeze at 5s. a ton, was 2s. per 1,000 in favour of the forced draught. But after allowing for extra labour in cleaning flues, interest on capital, depreciation, etc., as well as the very heavy items of 12s. 7d. a week for repairs to six furnaces, the net gain was put down at 9¾d. per 1,000 gallons. In a report by Prof. Kennedy and B. Donkin, jun.,† of the efficiency of a Lancashire boiler at Burnley, fitted with the Perret furnace, the heat expended in evaporating water under the special grate is put down as 4·6 per cent.; and reckoning only 3 per cent. for the power absorbed by the engine and fan, this shows a total loss of 7·6 per cent.

About seven years ago the author's firm took up the question (after having studied the subject of steam-jet blowers for a very long time previously) with a view of arriving at the best and most compact all-round arrangement for efficiency with special reference to flue boilers. After a deal of experimenting, the present form of apparatus was fixed upon, and up to the present time considerably over 2,000 furnaces have been fitted. The Meldrum furnace is an adaptation of the forced-draught closed ashpit system, the air being supplied by two steam-jet blowers to each furnace. These blowers are the outcome of long and careful experimenting, some thousands of tests having been made with blowers of all shapes, and nozzles of all kinds, and it is now confidently affirmed that the proportion of the blowers cannot be materially departed from without great loss of efficiency. Many people imagine that so long as a steam jet is inserted into a pipe the end is accomplished, but this is only true if economy of steam and pressure of air are no objects, and steam-jet blowers have been generally condemned through the wastefulness of badly designed apparatus, whereas tests made by the Admiralty and several large firms in England and on the Continent have verified the fact that under ordinary working conditions the quantity of steam used by the Meldrum blowers is only equal to about 2 per cent. of the total evaporation. The firebars employed with forced draught may be made with very narrow air spaces. Those used with the Meldrum furnace have only about 1-16th of an inch clearance so that nothing of value can fall through, and the saving in fuel from this cause alone is generally sufficient to provide all the steam required by the blowers. The bars are made interlocking, so that it is impossible to accidentally displace or lift a bar when cleaning the fire, as is often otherwise the case. The action of the steam upon the bars keeps them perfectly cool, so that clinker does not stick, and the bars last a very long time; in fact, with care, the bars will last for years, most of the bars originally fitted with the furnaces being still in use. The steam for the blowers is superheated by being passed into the furnace round the doors, and means are provided to ensure the re-evaporation of any condensed water that may enter the super-heater.

Another special feature of this furnace is the valvular dead-plate by the careful manipulation of which the primary and secondary supply of air, may be so proportioned that even, with bituminous coal, practically no smoke need be made. With the valve open a thin stream of air is admitted over the fire. An intimate admixture of air and gas takes place before they come in contact with the cool plates of the flue, and the smoke is thoroughly consumed. Having no moving parts, and positively nothing to get out of order, this system is especially applicable in a boiler-house where the greatest care is not generally available, and in actual practice it has been demonstrated that the upkeep of the apparatus costs practically nothing. The economy to be obtained depends largely upon the kind and cost of the fuel obtainable. In many large collieries, gasworks, and ironworks, the whole cost of the fuel is saved, refuse formerly carted away at considerable expense being the only fuel used. In cases where the boilers are slightly under power it has frequently been found that by applying this system the necessity of providing larger boilers has been avoided, and thus a large outlay for plant saved. When the chimney draught is insufficient through faulty construction of flues, or by the addition of extra boilers, it has frequently happened that the evaporation of the boilers has been increased as much as 25 per cent. With forced draught the heat of the waste gases may be utilised to a much fuller extent than with natural draught, and in this direction further economies may be looked for.

The Meldrum boiler has been designed with special reference to the economical utilisation of towns refuse or other very poor fuel, but may be used with advantage in burning any kind of fuel. The boiler is of the marine or return-tube type, but is provided with a door in the combustion-chamber, through which the unburnt incombustible residue of the fuel may be raked and generally for access to the furnace. The flue is made of ample diameter, and the grate placed at a considerable angle of inclination to facilitate raking the material forward. A feeding hopper is provided at the back end of the tubes, the fuel being tipped upon the platform overhead and raked into the hopper as required. The air for combustion is heated by the waste gases as they pass through the smoke-box. A tall chimney may be entirely dispensed with by substituting the exhauster, which is simply regulated so as to prevent the flame and gas blowing out of the clearing-door when the fire is receiving attention. The steam for the blower is superheated in the smoke-box. The Meldrum system of forced draught has also been somewhat largely adopted in the Midlands and South Wales in connection with puddling and heating furnaces. Similar advantages follow as with furnaces for steam raising. The bars may be placed much closer together, saving a very large percentage of fuel. Common fuel may be used very advantageously. The labour of clearing the grate is very much reduced, and also, as the maximum temperature is practically obtained, the charge may be worked off with greater rapidity, while the greater control of the air supply enables the operator to more readily adjust his flame to the required degree of activity with a consequent improvement in the quality of the finished product.

WORK OF AN ELECTRIC CURRENT.

The first of a course of six lectures, adapted to a juvenile audience, on "The Work of an Electric Current," was given on Thursday of last week by Prof. J. A. Fleming, F.R.S., at the Royal Institution. The lecturer began by pointing out that all bodies can exist in two conditions—electrified or non-electrified—and that ability to attract or repel other bodies is a sign of the former condition. He showed how pieces of india-rubber and dry brown paper may be electrified by rubbing them with fur, and how by virtue of their electrification they can be made to attract and adhere to other substances. The use of the gold-leaf electroscope to discover whether a body is electrified or not was explained, and it was proved that the electrification of a copper sphere can spread along a metallic wire or a wet silk thread, but not along dry silk. Dufay's discovery of the two kinds of electricity was then discussed, and it was seen that the gold leaves of an electroscope with a small negative charge came together when a glass rod rubbed with silk was brought near it, but separated on the approach of a stick of sealing-wax rubbed with catskin. The next point to which attention was drawn was that these two kinds of electricity—the vitreous, or positive; and the resinous, or negative—cannot be produced one without the other, and it was shown that when a glass rod is rubbed with flannel the glass and the flannel are electrified oppositely and in equal degrees. The charges of two oppositely-electrified spheres were proved to be neutralised when the spheres are brought into contact, the discharge being accompanied by a spark. Larger sparks were obtained from a Wimshurst machine, and the movement of the two kinds of electricity along the conductors between the plates of the machine and the knobs where the discharge took place was said to constitute an electric current. Another way of electrifying bodies was then explained. The quadrant electrometer was described and employed to show that, if an insulated plate of zinc is touched with one of copper, the two plates become oppositely charged. Volta's fundamental experiment was then performed. About a century ago he immersed two plates of silver and zinc in dilute acid, and found that, when they were connected by a conductor, positive electricity flowed from the silver to the zinc, and negative electricity from the zinc to the silver, the zinc at the same time being attacked by the acid. But when there was no connection between the plates no current flowed, and there was no action on the zinc. This arrangement of Volta's, called the voltaic cell, was the first efficient means of generating electricity in any quantity. The lecturer made a voltaic cell with a silver fork, a steel knife, and an orange, and demonstrated the existence of a current by means of a Pitkin galvanometer whose construction he had previously explained. He showed that no appreciable current can be obtained by using gold, silver, and an orange, the reason being that neither gold nor silver is acted on by weak acid, whereas for the construction of a voltaic cell it is necessary to select two metals, one of which is much more readily attacked than the other by the liquid in which they are immersed.

The second of the lectures was delivered on Saturday afternoon, when Prof. Fleming began by bringing forward some theoretical considerations as to the nature of what the old electricians termed a charge of electricity. He proved experimentally that the charge appeared to reside on the outside surface of an electrified cylinder, and that no signs of electrification could be found on the inside surface. By using a Leyden jar so constructed that its constituent pieces could be taken apart, he showed that the charge was apparently neither on the outside covering nor in the inside lining, but in the glass which formed the non-conducting medium between the two. He employed an analogy in explanation of the action of the jar. He supposed a piece of pipe to be rigidly closed at the ends and divided by indiarubber diaphragms into a number of separate compartments. A smaller tube, which could be closed by a stopcock, and which was fitted with a movable plug in its bore, was supposed to join the two extreme compartments, and the whole apparatus was considered to be full of water. If, now, the plug were moved a short distance a certain amount of water would be displaced, though it would not be able to move freely, and, if the stopcock were then shut, the indiarubber diaphragms would be kept in a condition of strain which would be relieved when the tap was opened. In like manner a charged Leyden jar might be considered as being in a condition of internal strain, which was relieved on discharge taking place. Prof. Fleming gave as a definition of E.M.F. any cause which displaced, or tended to displace, electricity in a body. He proceeded to further consideration of the methods by which the electric current might be produced. He showed a photo-electric cell consisting of two cylinders of tinfoil, separated by blotting-paper and immersed in plain water contained in a glass vessel. When this cell was exposed to the influence of light rich in chemical rays, such as was given by burning magnesium, the galvanometer gave evidence of the existence of a current. Several forms of thermo-electric couples were then exhibited and explained, and the use of a thermo-electric junction for measuring temperature was mentioned. Prof. Fleming next dealt with the production of a current by means of magnets, and went over some of the elementary facts of magnetism. He showed that a conductor conveying a current behaved exactly like a magnet, and could magnetise a piece of iron or steel placed within its influence, and he demonstrated the property possessed by a magnet of inducing a current in a surrounding coil of wire. Lastly, he dealt with the production of a current by the physiological action of certain living creatures, such as the torpedo and the gymnotus, or electric eel. A specimen of the latter was exhibited in a tank, and its electric powers proved by means of a galvanometer. Positive electricity was said to be given off from places near its head and negative from places near its tail. It was therefore able, by bending itself into the form of an incomplete circle, to send a shock through a small fish and perform what was now called an act of "electrocution." Faraday's acute speculations as to the mode in which the eel acted were mentioned, and it was suggested as probable that it possessed organs which resembled a secondary rather than a primary battery, and which enabled it to transform some of its energy into the form of electricity and store it up.

In his third lecture, delivered on Tuesday, Prof. Fleming began by discussing the chemical action of the current. Some liquids, he said, can be decomposed into their constituents by means of an electric current; such liquids are called electrolytes, and the products of the electrolysis ions, these terms having been coined by Whewell at Faraday's request. The lecturer then showed the electrolysis of a solution of sugar of lead into metallic lead and acetic acid, and pointed out that the deposition of lead upon the electrode became irregular if the process were hurried too much. This simple experiment he declared to involve the whole art of electro-plating, which he further illustrated by employing electricity to deposit copper on a carbon rod from a solution of sulphate of copper. He then proceeded to discuss the theory of electrolytic action, taking, as an example, the decomposition of chloride of silver. He supposed that one electrode was positively charged, and the other negatively; that each molecule of salt was not continuously composed of the same two atoms of silver and chlorine; and that each atom liberated from union with another carried with it a charge of electricity. He then employed a happy analogy drawn from a ball-room, possessing on one side a peculiar attraction for the ladies and on the other for the gentlemen. No pair of partners were to dance together for more than a few turns, but were to separate and either find new partners or yield to the attractions of one of the sides. The room would thus at any moment be full of pairs dancing and of individuals gradually making their way to one side or the other according to their sex. In the same way the vessel in which electrolysis was going on might be viewed as full of molecules of chloride of silver, and of disconnected atoms of chlorine and silver passing to one electrode or the other according to their polarity. The lecturer then stated the law that a given quantity of electricity was always able to liberate the same amount of ions from a particular solution, and, after explaining how an ampere may be defined from this fact, went on to give an experimental proof of its truth by showing that, if a certain tube could be filled with oxygen from the decomposition of water by a certain current in 20 seconds, it could be filled in 10 seconds if twice the current was employed. He then described the curious change which was undergone by two platinum plates used as electrodes, in the decomposition of water, for example. They were no longer the same electrically, but could give off a current as if they were made of zinc and copper respectively. The reason was that one was impregnated with hydrogen and the other with oxygen, and thus their electrical behaviour was altered. The secondary battery had been developed from this fact. Planté was the first to follow it up, and he found the best results could be obtained from lead plates. When these were used as electrodes in acidulated water, oxide of lead was formed on one and spongy lead on the other by the action of the current, and Faure, in 1880 or earlier, noticing this fact, conceived the idea of employing ready-made lead oxide on his plates, instead of making it by the current. Secondary batteries were now made both on Faure's and Planté's principles, since each had its advantages. Prof. Fleming then passed on to consider the heating effects of the current. He showed that a conductor through which electricity was travelling became heated, but to different degrees, according as the material of which it was composed was of a higher or lower electrical resistance. Thus a current passing through a chain made up of alternated links of iron and copper rendered the iron red hot, but left the copper unaffected to the eye. The heating effects of the current were also illustrated by passing it through a platinum spiral immersed in a little water, which soon began to boil, and its practical applications exhibited in the form of electric ovens, kettles, flat-irons, cigar-lighters, etc. It was proved experimentally that a conductor, when heated by the passage of a current, became elongated; and a Cardew voltmeter was shown, the action of which depended on this fact.—*The Times.*

MEMORANDUM ON LIGHT RAILWAYS IN BELGIUM.

The Board of Trade recently instructed Major G. W. Addison, R.E., to visit Belgium and investigate the construction and working of light railways in that country. Since then Major Addison has prepared the following report:

Light railways in Belgium are entirely in the hands of the Société Nationale des Chemins de Fers Vicinaux, formed by an Act of June 24, 1885, with the object of establishing light railways along the roads. Although the Government retains the power of granting concessions to private companies for similar undertakings, the Société Nationale has always the first offer. The capital of the Société Nationale is contributed one-fourth by the State and three-fourths by the provinces and communes directly interested in the construction of a line; private individuals may also subscribe, if they wish to push on a line, to the extent of one-third the capital required. As will be seen further on, the actual amount subscribed privately is very small indeed. The contributions of the provinces and communes are raised, with the assistance of the State, by means of 90 years' annuities at 3½ per cent. interest, which interest includes the sinking fund for the redemption of the debt in 90 years. If the annual profit on any line, after deducting working expenses, is insufficient to pay a dividend of 3½ per cent., the balance must be made good by the province and communes concerned. When more than 3½ per cent. is paid certain portions of the balance are allotted to the formation of (*a*) *fonds de prévision* for future improvements to the line, and (*b*) a reserve fund applicable to the system generally, and not only to the particular line earning the profit, as in the case of the *fonds de prévision*. In 1893 about 25 per cent. of the lines earned dividends of 3½ per cent. or more. Should a line fail to earn sufficient to pay working expenses, the loss to that extent falls upon the Société Nationale, but the latter is not responsible for the interest, etc., of the annuities.

The headquarters of the society are in Brussels, and it is administered by a Board consisting of a president, four members, and a general manager; the president, two of the members of the Board, and the general manager being nominated by the King, all the society's operations are, practically speaking, controlled by Government. There is also a "Comité de Surveillance" of six members, appointed by the annual general meeting, at which each province and commune is represented by one delegate, and private subscribers have a certain number of votes. The demand for a new line must come from the council of the commune to the National Society, giving full information as to the population and industries to be served by the proposed line, and the route the line should take. The commune must undertake to repay to the society any expenses incurred in making surveys, etc., should the line not be constructed, and they must furnish details of their financial position and ability to subscribe their share of the required capital. The society, after making estimates of the cost of constructing and working the line, and arranging with the provinces and communes concerned the share which each should contribute towards the capital, forwards a report, with all plans and documents, to the Minister of Agriculture and Public Works; the latter decides whether any public enquiry is necessary or not before the concession is signed by the King. The lines are made by contract under the supervision of the society. It is calculated that 2,000f. per kilometre (£128 per mile) should suffice to repay to the society preliminary expenses and the cost of watching the work of construction.* When finished, the lines are handed over to subsidiary companies to maintain the permanent way, keep up the rolling-stock, and work the lines generally. These companies receive a fixed percentage of the gross receipts, with, generally, but not always, a guaranteed minimum of 2,000f. per kilometres (£128 a mile) a year. A separate account, both as regards construction and working, is kept by the Société Nationale for each line, and they furnish an annual report giving very full details of everything. From the report of 1893 I find that:

(1) The society was then working 58 lines, with a total mileage of about 730 miles; four lines, 40 miles in length, were in course of construction; and projects were under consideration involving about 900 miles additional.

(2) The gauges of the above 62 lines were: about 615 miles, 1 metre gauge; about 125 miles, 1·067m. gauge; about 30 miles, 4ft. 8½in. gauge. The intermediate gauge lines (1·067m.—*i.e.*, about 3ft. 6in.) form extensions of the Netherlands "Vicinaux" railways. Practically, therefore, the Belgian lines may be considered a metre gauge system.

(3) The subscribed capital amounted to about £2,350,000, subscribed in the following proportions—viz., by the State, 27 per cent.; by the provinces, 28 per cent.; by the communes, 41 per cent.; by private individuals, 4 per cent.

(4) The cost of constructing the lines, providing rolling-stock, etc., averaged £2,688 per mile—the sum paid for land being less than £220 per mile of line.

(5) The system included sidings at 62 stations of the main railway lines, and 93 sidings constructed for private companies and individuals. Of the latter about one-third are in the interest of agriculture.

(6) The society had 245 locomotives, 663 passenger carriages, 1,574 wagons and luggage vans. The locomotives are principally of 18 tons weight, but there are a few lighter, and some up to nearly 30 tons in weight. Of the wagons, more than 70 per cent. carry 10 tons, the remainder being for freights of five tons (a few also for 20 tons).

(7) The working expenses were 71·31 per cent. of the gross receipts, the expenses including 175f. per kilometre (about £11 per mile) to the society for administration, etc.

(8) The receipts from passengers and goods respectively were 72 per cent. and 28 per cent. of the total.

(9) The mean recent dividends paid on all the lines are: 1890, 2·65 per cent.; 1891, 2·75 per cent.; 1892, 2·76 per cent.; 1893, 2·80 per cent. In 1893 four lines were unable to pay working expenses, and there appears to be a loss to the society on the working of those lines to the end of 1893 of rather over £3,000. On the other hand, the society had a reserve fund of between £8,000 and £9,000, and the *fonds de prévision* amounted to nearly £5,000.

(10) During 1893 no accident is said to have occurred to any person due to collisions or to the train leaving the rails. The actual number killed and injured were: passengers killed 5, injured 3; companies' servants killed 0, injured 3; other persons killed 20, injured 7. In nearly every case of death contributory negligence is claimed to relieve the company working the line from blame.

I thought it desirable to inspect a line intended primarily to serve an agricultural district, and with this object the line from Andenne to Eghezée was selected. M. de Burlet, the general manager of the Société Nationale, kindly sent one of his engineers, M. Paul Berger, with me. This line is about 12½ miles in length, and is mainly dependent upon its goods traffic, which produced last year about 60 per cent. of the gross receipts of the line. Like all the Vicinaux railways, it is constructed on the road, excepting where steep gradients, etc., make slight diversions desirable. Usually a line of way is formed at one side of the road, raised slightly by ballast etc., and separated from the remainder of the road by kerbstones; it resembles a footpath alongside a country road. In this way the railway is not available for ordinary carriage traffic, nor is it used by pedestrians. Through villages, and where roads have to be crossed, the line is of the usual tramway type.

The line is of one metre gauge, with steel rails weighing 21½ kilos (42lb.) per yard. In the towns, I believe, they use a deeper rail, weighing about 60lb. per yard. The rails are of the "Vignolles" type, secured by dog spikes to creosoted sleepers about 4ft. 8in. by 8in. by 4in. Points are worked in the country by a lever, at the side of the line, and in towns by a key, fitting a screw-head placed between the rails. I did not obtain details of the curves and gradients of the Andenne-Eghezée line, but, as examples of the Vicinaux system, I take three lines, amounting to 45 miles in length, where the sharpest curves are 30 metres, 35 metres, and 40 metres respectively—*i.e.*, about one and a half to two chains radius. On the same lines there are gradients of 1 in 20 and 1 in 25. Round the very sharp curves gauge ties are used to prevent the rails from opening out. Guard rails are only used in towns. The speed is limited, by regulation, to 30 kilometres (about 18 miles) in the country and six miles per hour in towns and through villages; the time allowed in the time table for the journey from Andenne to Eghezée, 12¼ miles, averages one hour 25 minutes, but one train in the day each way only takes about one hour five minutes. On another line, Ostende-Furnes, which is chiefly a passenger line, the trains take about 1¾ hours on a journey of 20 miles.

The engine of the Andenne line, 18 tons weight, had six wheels coupled, each of 3ft. diameter; all moving parts were cased, and it was driven from either end (the driver, of course, always being in front). It was, in fact, an ordinary tramway locomotive. The engine was only provided with a hand screw brake. I notice in the police regulations, issued from the office of the Minister of Agriculture, etc., that the brakes on the engine wheels should be sufficient alone to stop a train on the steepest gradients in a length of 30 metres (33 yards). They were trying a simple form of continuous brake actuated by either the driver or guard releasing a cord; upon which weights fell and applied the brakes; the cord passed over the tops of the carriages or wagons (to which this arrangement is equally applicable). The engine always carries two men—a driver and a stoker.

The train in which I travelled was composed, at starting, of one goods wagon next to the engine, one passenger carriage, and one *fourgon* or luggage van; subsequently we dropped the goods wagon, but picked up three more wagons. The mixed trains usually have one van in front of the train in one direction and in rear on the return journey. The van carries any

* This amount is included in all estimates.

Digitized by Google

passenger luggage and goods of small bulk; when not employed elsewhere, the guard rides in the van and makes out his way-bills, etc. With the suburban passenger trains there is usually no van, but the society has a certain number of vehicles forming a second-class compartment and a small van. Vans have a post office letter-box in which letters can be posted at the various halting places. The wagons, carrying 10 tons of goods, weighed about four to five tons, and had four wheels coupled. They were of various patterns, according to the purposes for which they were intended to be used. The carriages on the Andenne-Eghezée line are about 20ft. in length to the ends of the buffers, and about 8ft. 3in. in width; they are divided so that one-third forms a first-class and the remainder a second-class compartment, with seats across the carriage, a central passage, and doors at the ends opening from platforms. They are provided with a screw hand-brake on one platform. There are various patterns of carriages in use on other lines. On one line running into Brussels I noticed a carriage nearly 40ft. long, with bogies at each end; I also saw some carriages with a very small wheel base, short bodies over the wheels, and large outside platforms. In all, however, the seats were placed across the carriages, and not along the sides. If more than two passenger carriages go with the train, they are supposed to have a second guard or brakesman. The length of the train is fixed for each line according to the gradients, the brakes in use, etc., but as a general rule it is limited to about 130ft. (engine, van, and five carriages or wagons as a maximum).

There were several sidings on the Andenne-Eghezée line, at the side of the road, so that carts could draw up alongside the goods wagons either to load or unload them. The running line is then outside the siding, on land acquired for the purpose. Sidings on the level usually had two dead-ends, roughly made with a bank of earth and a few timbers. The stoker acts as foreman shunter at the sidings. The train only picks up loaded wagons, and does not stop to load *en route*. There were no signals of any description in use on the line I examined. M. de Burlet informed me they were only used at specially dangerous points, such as level crossings over main lines of railway, where there are safety points, and a signal indicates to the driver when he is approaching these points. Before sunrise, after sunset, and during foggy weather the locomotive carries two white lights in front, one on either side, and a green light is attached to the tail of the train. A room in an inn generally forms a waiting-room for passengers, and a place where parcels can be left either until called for or to be picked up by the train. No tickets are, however, issued, or other ordinary station business transacted. I believe it is not usual to make any payment to the proprietor of the inn, who gladly affords these slight facilities in return for the custom brought to the house. In addition to the stations as above, there are also fixed points (with a notice board only) where the train stops if there is anyone to pick up or set down, such as at important cross roads, etc.

At Eghezée, the Vicinal railway connects with the main railway system; there is, however, neither here nor elsewhere, any physical junction of the metre gauge with the 4ft. 8½in. gauge line. Passengers alight in the road, near to the main-line station, and there is a goods siding alongside a similar siding of the main line—that is all. Only the Vicinaux trains of 4ft. 8½in. gauge run into the stations of the main lines. The only other point I have to mention in connection with the working of the Chemins de Fer Vicinaux, is that the police regulations issued by the Minister of Agriculture, etc., fully recognise the necessity for protecting the railway as well as the public. Riders, drivers of carriages, carts, etc., are warned upon the approach of a train to keep at least 5ft. clear of the rails; if the rider or driver is not sure of his horse, he is enjoined to lead it until the train has passed. Before crossing the railway, persons are instructed to ascertain that no train is near. The level crossings of roads, excepting in a few instances, are not watched or guarded in any way.

INTERDEPENDENCE OF PATENTS.

Two cases have just come before the courts on this subject—Semet and Solway's prolongation petition, before the Privy Council on December 8, and the case of Muirhead *v.* The Commercial Cable Company, on December 18. In the former, the question discussed was the effect of European patents on a British patent; while in the Muirhead case the point was the effect of a British patent on a United States American patent. The patent laws of most countries provide for the cesser of the domestic patent on the lapse of a prior foreign patent for the same invention. This was also the rule in England prior to January 1, 1884; and in considering British patents it is necessary to consider those granted before that date separately from those granted since, for the Patent Act, 1883, repeals the 1852 Act, and Section 25 of the 1852 Act (which dealt with this point) is not reproduced. Consequently, the lapse of foreign patents has no effect on British patents granted since the Patent Act, 1883, came into force. With regard, however, to patents granted before January 1, 1884, the law is not quite so clear, as Section 113 of the Patent Act, 1883, declares that the repeal is not to "affect the past operation of any of those enactments or any patent granted . . . or liability acquired. . . ."

This point has been the subject of discussion in a somewhat recent case. In the year 1891 the owners of Jablochkoff's patent for dividing electric light applied for a prolongation. The Privy Council could not see their way to advise a prolongation of this patent, chiefly on the ground that the patent was invalid; and although the Judicial Committee did not express a decided opinion on the question, it was evident they considered that the expiry of prior foreign patents was a very serious obstacle in the way of a prolongation.

Semet and Solway's prolongation case can be differentiated from Jablochkoff's. In Jablochkoff's case the expired patents were prior to the English patent, and consequently within the express words of Section 25, and, moreover, had expired before January 1, 1884. In Semet and Solway's patent the foreign patents were all dated after the English patent, and the utmost that could be urged against the prolongation was that this case was within the spirit of Section 25. The Lords of the Privy Council held, however, that Section 25 of the Patent Act, 1852, did not apply, and that they had power to recommend a prolongation. Having satisfied themselves on the merits of the invention, their lordships advised a prolongation of five years.

Muirhead's action against the Commercial Cable Company was one of extreme interest, as it related to Muirhead's system of duplex telegraphy, whereby two messages can be despatched in contrary directions along the same wire. So far as the law point is concerned the case is comparatively simple. Muirhead took out an English patent in 1876 for duplex telegraphy, and in 1880 took out a United States patent also for duplex telegraphy. The 14 years of the English patent ran out in 1890; whilst the American patent would run for the full 17 years—namely, to 1897—unless cut short by reason of the expiry of the English patent. By the United States law the United States patent would expire with the British patent, supposing it covers the same invention. The simple point, therefore, came to this—was the United States patent of 1880 the same as the British patent of 1876? The judge of first instance held that the two were different, and now the Appeal Court held (Lord Esher dissenting) that the two inventions were substantially the same. The result of the litigation is that there is a balance of judicial decision in favour of each litigant. Although the action is nominally for £3,500, the amount in dispute is about ten times that sum. If the United States patent is in force the Commercial Cable Company, who are licensees, will have to pay royalties until the end of the 17 years. The case will accordingly be the subject of appeal to the House of Lords. A case which brings into discussion United States law is of interest, and although the United States law is regulated by their revised statutes, it is possible to see that the underlying principles are common to both countries. Those persons, however, who have to deal with patent procedure in Washington know that there is often a great apparent difference between British and United States specifications for the same invention. This is the case particularly with the claims, and consequently too much reliance cannot be placed on apparent differences between the United States and British specifications. The decision of the majority of the Court of Appeal will be found to be correct.—*G. B. E. in the "Law Journal."*

COMPANIES' MEETINGS.

ELMORE'S FOREIGN AND COLONIAL PATENT COPPER DEPOSITING COMPANY, LIMITED.

The fifth annual ordinary meeting of this Company was held at Cannon-street Hotel on Monday, Mr. F. L. Rawson in the chair.

The Chairman moved the adoption of the report and accounts. He pointed out that the general expense of carrying on the business of the Company was almost one-third less than before The Board had decided to write off the value of the deferred shares in Elmore's American and Canadian Patent Copper Depositing Company on the ground that there was no hope of such shares ever realising anything like their face value. This, however, did not represent any actual pecuniary loss, as the Company would continue to hold the shares for whatever they might ultimately realise. After providing for this reduction in the Company's assets, there remained a surplus of £166,417 5s 5d. The past year had been a most trying one, but the Board believed that their difficulties, which were chiefly of a financial character, had now been overcome. The French company had escaped liquidation, and the German company had attained to a perfectly satisfactory position from a manufacturing point of view. The result of the present working of the companies here and on the

Digitized by Google

Continent confirmed the directors' belief that the statements made by the Company would be more than borne out. Negotiations were on foot for the sale of the Belgian, Indian, Italian, Russian, and Spanish patents. In order to raise the necessary capital to carry on the Company it was proposed to issue £5,000 of first mortgage debentures.

Mr. J. J. Atkinson seconded the motion, which was agreed to.

The question of raising fresh capital was then discussed. It appeared from the chairman's statement that the directors had met the most pressing financial claims against the Company during the year.

On the motion of the **Chairman**, Mr. Shurmur (the secretary) was elected as director in the place of Mr. W. Elmore, who retired.

ELMORE'S AMERICAN AND CANADIAN COPPER DEPOSITING COMPANY, LIMITED

The annual meeting of this Company was held on Monday last, Mr. J. J. Atkinson in the chair.

The **Chairman** said the directors would have been very glad had they been in a position to announce the sale of the property during the past year, but there had been no offer for it at anything like a satisfactory figure, and there was no likelihood of a sale until they were in a position to show beyond all question the commercial value of the patents. The Company's friends in America were absolutely satisfied in regard to the merits of the process on every point except that of the cost of production, although upon this point the directors could furnish expert testimony of the highest authority. However, until the European companies could show a substantial profit for the working of the patents their Company was not in a position to insist upon a proper purchase price for their rights.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Saint-Die (Vosges, France).—The Municipality invite tenders by February 1 for the concession for a central electric light station for the town.

Louvain (Belgium)—Tenders are invited by February 1 by the local authorities at the Hotel de Ville for a concession for an electric tramway from the railway station to the Grand Place, Louvain.

Hanley.—The Corporation of Hanley are prepared to receive tenders for the supply and erection of plant, etc., at the central electric light station. Tenders are to be delivered by January 5. Particulars appeared in our issue of last week.

Bristol.—Tenders are invited for the installation of the electric light at the Guildhall and a portion of the Council House, for the Corporation. Plans may be seen at the office of the city electrical engineer, Mr. H. Faraday Proctor, A.M.I C.E., M I.E.E , Temple-back, from whom specifications may be obtained. Tenders to be sent to the chairman of the Finance Committee, the Council House, Bristol, by January 18, endorsed "Tender for Electric Light Installation."

Stockport—Tenders are invited for providing and fixing complete a fuel economiser, for the Corporation. Plans of the boiler-house, now in course of construction, together with the specification of the work required, can be seen and form of tender obtained at the office of Mr. A M. Fowler, 1, St. Peter's square, Manchester. Tenders to be delivered at the office of Mr Walter Hyde, town clerk, 2 Lord-street, Stockport by January 16, endorsed "Tender for Economiser." The standard rate of wages in the district will have to be paid by the contractor in the construction of the work.

Birmingham.—The committee of the Birmingham Municipal Technical School invite tenders for the installation of the generating plant, fittings and appliances for both the electric lighting and transmission of power by electricity in the new school. Plans of the building may be seen, and specifications and forms of tender obtained, at the offices of Messrs. Hy. Lea and Thornbury, consulting engineers, 38, Bennett's-hill, Birmingham, on a deposit being made with them of £2 2s., which will be returned on receipt of a *bond fide* tender. The committee do not bind themselves to accept the lowest or any tender, and no tender will be considered except upon the prescribed form and accompanied by an undertaking that not less than the minimum standard rate of wages current in the district is paid by the contractor and sub-contractors (if any). All tenders must be sent in to Mr. Geo. Mellor, secretary, endorsed "Tender for Lighting," on or before January 12.

RESULTS OF TENDERS.

Taunton.—The Fowler-Waring Cables Company have obtained the contract, at £681, for the supply to the Town Council for the necessary cables, etc., for making the house connections in connection with No. 2 sub-station.

Belfast—The contract for the electric lighting of the Belfast Exhibition, to be opened in the Linen Hall grounds early in April, has been placed in the hands of Messrs. William Coates and Son, of Fountain-street, Belfast, to be carried out under the superintendence of their electrical engineer, Mr. E. S. Dashwood. The plant, which will consist of steam and gas engines, will be capable of supplying 100 2,000-c p. arc lamps and 1,000 16-c p. incandescent lamps with reserve. This firm is also engaged on several small contracts in the city and neighbourhood.

BUSINESS NOTES.

Hull.—The number of customers for the electric light is 268 as against 134 a year ago.

Killarney.—The question of the electric lighting of Killarney District Lunatic Asylum is being considered.

Aberdeen.—The new police offices will probably be occupied by the end of the summer. They will be lighted electrically throughout.

High Wycombe.—Mr. Hammond has presented a report to the Town Council as to the proposed introduction of the electric light.

Hove.—The Town Council have instructed their surveyor to report on the advisability of lighting Church-road and other thoroughfares by electricity.

Dundee.—A proposal has been made to light the tramcars and omnibuses by electricity, the same method being adopted as on the Glasgow Corporation cars.

Edinburgh.—A Christmas carnival is being held in the Waverley Market, and a brilliant electric illumination has been carried out by Messrs. King and Co., Leith.

West India and Panama Telegraph Company.—For the half-month ended December 31 the receipts show a decrease of £542 as compared with the corresponding period of 1893

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 30th ult. amounted to £837, as compared with £619 in the corresponding week of the previous year.

Luton.—The Town Council have been informed by the clerk that he has received from the parliamentary agents prints of the draft provisional order for the supply of electricity for the borough of Luton.

Exhibition at Salisbury.—Mr. E. R. Dale, A I.E.E., of Sherborne, Dorset, asks those firms who wish to be represented at the forthcoming Electrical Inventions Exhibition at Salisbury to send particulars to him.

Devonport.—The Town Council have received a letter from the solicitors of the Brush Electric Light Company stating they do not intend to proceed with the application for a provisional order to light Devonport by electricity.

Worcester.—There have been 36 candidates for the position of electrical engineer to the borough. The subject is still in abeyance, owing to differences of opinion between the Electricity Committee and other members of the Council.

Direct Spanish Telegraph Company, Limited.—This Company has opened offices at Liverpool and Manchester for the reception and delivery of telegrams exchanged with Spain by their direct cable system between England and Spain, *vid* Falmouth-Bilbao.

Andrews's Foreign Syndicate, Limited.—This Company has been registered, with a capital of £4,000, to acquire and deal with the patented invention of J. D. F. Andrews and J. C. B Andrews for improvements in electric conductors and joints therefor for electric lighting.

Partnership.—Mr. Henry Edmunds, 39, Victoria-street, Westminster, and Salford Manchester, has brought into partnership Mr. Godfrey Blundell Samuelson, the son of Sir Bernhard Samuelson, Bart , M.P. The style of the firm will remain W. T. Glover and Co., as heretofore.

Hobart Electric Tramway.—The Hobart Electric Tramway Company. Limited, gave notice last week that interest on coupon No. 6 of first and second mortgage debentures would be payable at the Commercial Bank of Scotland, Limited, 62, Lombard-street, London, E.C , on and after 1st inst.

Appointments.—Mr A. G. Roe of Bournemouth, and Mr. G. H Swetenham, of Ealing, have been appointed electricians to the P. and O steamers "Kaiser-i-Hind" and "Shannon" respectively. They qualified under Mr. Ronald A. Scott, M I.E.E., Acton Hill Electrical Engineering Works, Limited.

Coventry. The Town Council have received tenders for electric meters from the Westinghouse Electric Company, Electric Construction Company, Limited, British Thomson-Houston, Limited, General Electric Company, Messrs. Chamberlain and Hookham, and Mr. C. A. Muller. The tenders are under consideration.

City and South London Railway.—The receipts of the Company for the week ended December 30 were £859, against £837 for the corresponding week of 1893, or an increase of £22. The total receipts for the past half-year amount to £23,306, as against £21,886 in the corresponding period of 1893, an increase of £1,420.

Kensington.—There has been issued the Kensington Vestry report for the financial year March 26, 1893, to March 25, 1894, in which reference is made to the revocation of the order of the House-to-House Electric Light Supply Company, Limited, as regards a portion of the area. This took place on December 1, 1893.

Payment of Coupons.—The Salt Lake and Ogden Gas and Electric Light Company gave notice last week that the coupons of the company, due on the 1st inst., would be paid at the National Provincial Bank of England, Bishopsgate-street, London, E.C., or at the Farmers' Loan and Trust Company, New York, on and after that date

Western and Brazilian Telegraph Company.—This Company has received from its representative in Rio de Janeiro the following telegram, dated December 26: "Budget Bill containing purchase clauses signed by President of Republic on Christmas Day." For the week ended December 22 the receipts were £3,141, and for the past week £2,829.

Digitized by Google

Sunderland.—The Town Council are going to appoint an assistant to Mr. Vesey Brown at a salary of £120, owing to the increased duties which will have to be undertaken by the electrical department when the supply of current is commenced. The public library is to be lighted electrically. Applications have now been received for 1,173 lights.

Silveroid Company, Limited.—This Company has been registered with a capital of £400 to carry into effect an agreement for the working of a secret process for the electrical deposition of silver upon metals usually electrotyped, made between C. H. Woolf and A. E Hayman of the one part, and S. F. St. Germain, S. Bertram, B Van Praag, A. Sims, H. G. Campion, and H. S. Simmons of the other part.

Electric and Inventions Exhibition.—An electric and inventions exhibition is to be held in Salisbury. It is expected that the exhibition will be opened about the end of this month. Intending exhibitors are requested to send full particulars for catalogue to the promoter and general secretary, Mr. E. R. Dale, Sherborne, Dorset, and care of Mr. J. Parsons, 100 Bedwin-street, Salisbu y.

City.—The new buildings of the Commercial Union Assurance Company are to be lighted throughout by means of electricity The directors have appointed Messrs. Handcock and Dykes, Victoria-street, as the consulting engineers to supervise the work throughout. and Messrs. Hayward Tyler and Co., Whitecross-street, have the contract for the installation. The number of lights will probably be about 600.

New Firm.—Mr. Arthur H. M. Francis, formerly branch manager in Dublin for Woodhouse and Rawson United, Limited, and late representative of the Edison and Swan United Electric Light Company, Limited, for the East, South and West of England, has formed the new firm of Francis and Spilsbury, electrical engineers and general electrical agents, Mansion House-chambers, 20, Bucklersbury, Queen Victoria-street, E.C.

Gilbert Gilkes and Co., Limited.—This Company has been registered with a capital of £20,000 to acquire the business of a civil and mechanical engineer carried on by Gilbert Gilkes, as Gilbert Gilkes and Co., at the Canal Ironworks, Kendal, Westmoreland, and to carry on the business of ironmasters. steelmakers, iron and steel manufacturers, mechanical and electrical engineers, toolmakers, brassfounders, tinplate-workers, metalworkers, boilermakers, millwrights, etc.

Chelmsford.—The Chelmsford Electric Lighting Company, in reply to the petition of consumers asking that the electric supply should be continued for as many hours as possible during the dark days, state that they will endeavour to meet the request as far as lies in their power. It is absolutely necessary, however, to turn off the current for at least one hour a day for testing purposes, and for a longer period than this for a few days for the purpose of connecting new customers to the system. The fixed hours during which the current will be switched off every day will be from 12 to 1.

Universal Electrical Fittings Company, Limited.—This Company has been registered with a capital of £6,000 to carry on the business of metallurgists, metalfounders, metalworkers, woodworkers, toolmakers, electrical instrument makers, electrical contractors, manufacturers of and dealers in or affixers of dynamos, lamps, meters, transformers, conductors, switches, lampholders, brackets, electroliers, and all or any kind of electric materials, apparatus, appliances, articles, and things in connection with electric lighting, electric traction, telegraphs, telephones, or any other branch of electrical work.

Edmonton —The local authority has received the following tenders for telephonic communication and electric call fittings and for maintenance: F. E. Stewart, £122. 2s, ordinary maintenance £17, special £22; Vaughton and Co, £193, maintenance £28; Private Wire and Telephonic Institution, £268, maintenance £20; J. Faulkner, £245, maintenance £35; J. E Cullum, £139, maintenance £13; Blenheim and Co, £277 5s, maintenance £16 10s; Consolidated Telephonic Construction and Maintenance Company, £307, maintenance £9; National Telephone Company, £175, maintenance £24; J. Sax and Co, £244 10s. These tenders have been referred to the engineer.

Light and Heat Exhibition, 1895 Incorporated.—This Company has been registered as a guarantee company. For the purposes of registration the Company is declared to consist of 100 members, each liable for the sum of £1 in the event of winding up. Object: to adopt and carry into effect an agreement, made October 4, 1894, between the Kensington Woodhouse Park Syndicate, Limited, of the one part, and J. Furley, J.P., of the other part, for the acquisition of the premises, etc., known as Woodhouse Park, Shepherd's Bush, and to carry on in London during the year 1895 an exhibition of manufactures, inventions, and objects of interest connected with actual means of lighting in all its branches.

Appointments Vacant.—The British Guiana Postal Telegraph Department want an assistant electrician. Applicants must have a thorough knowledge of the construction of telegraph and telephone lines. be conversant with the adjustment and working of telegraph and telephone apparatus, and able to make tests of submarine cables. The salary is £300 per annum and travelling expenses. Engagement for three years and free passage out and home. Applications are to be sent to Mr. W. H. Preece, General Post Office, by 7th inst.—The Sunderland Corporation want an assistant electrical engineer at a salary of £120. Applications are to be made by 23rd inst.—A clerk of works is required by the Bristol Corporation to superintend the electrical installation at the Town Hall.

Electrical Advertising.—Some interest has been excited by the appearance on the front of the Empire Palace Theatre, in Edinburgh, of an electric signboard on which is flashed out in coloured lamps alternately the words "Empire" and "Palace." This device, brought out by Mr. W. F. King, of Messrs. King and Co., Leith, consists of a large board forming a dark background, on which are mounted several groups of coloured electric lamps. To these current is supplied from the dynamo which lights the building itself. The groups of lamps, to the number of 130, are intermingled one with the other, some of the lamps being used for both words in common, and the whole is lighted in such a way that one word appears in the position previously occupied by the other. The general effect of the arrangement is striking.

Plant for the Transvaal.—Speaking on Monday at the ninth ordinary general meeting of the Transvaal Gold Exploration and Land Company, Limited, held at the Cannon-street Hotel, Mr. W. M. Farmer (the chairman) said: "One thing most important is increased primary power. There is a splendid river running through the property, and we can tap it higher up and treble the present power. We can, by means of electricity, convey the power to the various positions of the property where we hope we shall be justified in erecting new stamps. For this we are now awaiting surveys and specifications for piping for a new race. The work will be put in hand whenever the specifications arrive, and when we are provided with the power we can then undertake to deal with the low-grade ore, of which there is a large quantity available."

Mersey Railway Company.—In accordance with the Standing Orders of Parliament, the Mersey Railway Company has deposited a copy of its Bill for next session in the Private Bill Office of the House of Commons. The Bill, which contains 18 clauses, seeks power to raise £50,000 additional debenture stock, ranking equally with the existing £275,000 4½ per cent. first debenture stock. This new stock is required for the purpose of providing a station for generating electricity, and for purchasing the necessary appliances for working the railway by electrical power. The Company also asks Parliament to authorise it to create a further amount of £150 000 first debenture redemption stock, for the purpose of redeeming the existing debenture stock of the Company. This stock is to be in addition to the £600,000 of similar stock which was authorised to be raised for the same purpose by Section 26 of the Mersey Railway Act of 1888.

Temporary Electric Lighting —On the occasion of the ball which was given in honour of the *début* of Lady Helen Stewart, at Wynyard Park, on Thursday of last week, the electric light was very much in evidence, being used with the most successful and brilliant effect. The ordinary installation at the Hall numbers no less than 1,200 lamps, and this was supplemented on the evening in question by a temporary installation of about 400 extra incandescent lights, whilst four 2,000-c.p. arc lanterns were also put on for external illumination, chiefly the north front of the Hall, where guests alighted. All this was done without extra engine power being required. thus showing the advantage of the duplicate method of working. The permanent and temporary installations were laid down by Messrs. Drake and Gorham, of Princes-mansions, Victoria-street, London S W. Mr. Drake, junior, of the firm, and Mr. Jenkins, the resident electrical engineer at Wynyard Park, superintended the lighting arrangements. Messrs. Drake and Gorham have a commission from Lord Londonderry to light his lordship's town house, Londonderry House, Park-lane, by an installation of about 1,000 lamps.

Leeds.—The City Council resolved at its meeting in October last to authorise the Corporate Property Committee to make an arrangement with the Yorkshire House-to-House Electricity Company for the supply of electric light for the Town Hall and Municipal Buildings for a period of two years. It was stated that the electric lighting plant at the Municipal Offices was obsolete, and it was considered advisable to obtain a supply from the House-to-House Company rather than lay down new machinery. A draft agreement with the company was afterwards submitted to the committee and approved, but the committee did not agree to the proposed insertion by the company of a minimum quantity to be paid for by the Corporation. This led to an interruption of the negotiations, and on Monday last the Corporate Property Committee met, under the presidency of Alderman Sir Edwin Gaunt, to consider the question of laying down new electric lighting plant at the Municipal Offices. Instead of considering this business, however. the committee authorised Sir Edwin Gaunt and Councillor J. Green Hirst (chairman of the Corporate Buildings Sub-Committee) to enter into further negotiations with the House-to-House Electricity Company, who, it was understood, might be willing to modify their previous proposal.

Ealing.—The Local Board at their final meeting received a letter from Messrs. Cornforth and Reacher, Mansion House-buildings, London, with reference to the loan of £26,000, at 3½ per cent. interest, required by the Board for electric lighting and other purposes. Messrs. Cornforth and Reacher offered to supply this money at a commission of three-quarters of 1 per cent., they bearing the legal charges associated with the loan. Mr. Baker Hays, in moving that the offer be accepted, remarked that it was the best offer the Board had had, and in view of the fact that by the action of the Local Government Board the Board were precluded from issuing stock or debentures he recommended its acceptance by the Board. Mr. Green seconded the motion, which was carried, subject to the brokers out of the commission named paying for the stamps and defraying the legal charges incidental to the loan. The Electric Lighting Committee reported that up to the present date 64 applications had been received for private installations of the electric light, involving a supply of

Digitized by Google

4,033 8 c.p. lamps. Of these requested connections, 50 had been made, with a total of 2,684 lamps; the remainder, it was expected, would be put in connection in about three weeks. The street arc lamps erected and working numbered 44 out of 70; it was anticipated that by the end of the week six more would be erected and working, making 50 in all.

Glasgow.—The growth of the electric lighting scheme of the Corporation has been greater during the year than the most sanguine of its promoters expected, and it is probable that a second supply station will have to be put under way at no distant date. Nearly all the important buildings in the central districts of the city are provided with electric light either in connection with the Corporation supply or from their own installations. In some cases both connections are made. Electric motors, it is reported, are now used in Glasgow for driving ventilating fans, sewing-machines, and other light machinery. A great expansion has taken place in ordinary electric lighting business beyond the limits of the Corporation supply. In the West of Scotland, Messrs. Wm. Baird and Co have been pioneers in the adaptation of electric plant to coal-mining. Messrs. John Watson and Co, the Bent Colliery Company, the Coltness Iron Company, the Merryton Coal Company, the Carron Iron Company, and others are now applying electricity underground to such purposes as pumping, hauling, coal-cutting, etc. An installation of electric light has been fitted up in the new buildings of the Sun Fire and Life Insurance Company in Glasgow, the current being supplied by the Corporation, and an electric hoist gives easy access to the upper floors. The sub-committee appointed to consider the advisability of electrically controlling a series of public clocks by a system have held a meeting, at which a report was given in by Prof. Becker, of the university, giving details how such a system could be worked out, and after considering the same it was agreed to instruct him to make the necessary tests to ascertain the efficiency of the scheme proposed.

Tunbridge Wells.—The Callender Bitumen and Cable Company, Limited, of 101, Leadenhall-street, E.C., who are the makers and contractors for laying the underground mains, recently commenced operations. A start was made with the laying of the cables opposite Mount Ephraim House, and the work is being continued along the Mount to the junction at London-road. Messrs. Callender's resident engineer is Mr. Henry Schiassi. The type of mains adopted is concentric lead, sheathed and armoured, the dielectric itself being jute fibre impregnated with bitumen under heavy pressure. The mains are laid direct into the ground, the cables possessing sufficient mechanical strength necessary to withstand all ordinary rough usage and heavy traffic without injury. The great advantages arising from the use of this solid buried system of cables are the ease, rapidity, and economy with which the laying can be effected. The mains will be continued down the London-road to the Kentish Corner. The work will then be commenced from the electric light station, up Stanley-road to the Camden-road, turning into Calverley-road, terminating at the junction with Mount Pleasant. It is then continued down Mount Pleasant-road to the High-street, by the Kentish Corner, thence through the London-road to the Pantyles, terminating at the further end near the pump-room. A main will also be laid through the Monson-road, connecting with the cable in Mount Pleasant. Another main will start from the corner of Calverley-road, up Grosvenor-road to its junction, near the fountain, with Mount Ephraim. There will be four sub-stations, and as at present arranged, these will be at Waymark's corner, about midway down Mount Pleasant-hill, the centre of High-street, and on the Pantyles. It is expected that the work of laying the mains will be completed about the middle of next month.

Islington.—On Thursday last week Mr. Samuel Lambert, chairman of the Electric Lighting Committee of the Islington Vestry, laid the foundation-stone of the central station which is to be built at the west end of Eden-grove, Holloway, adjoining the Great Northern Railway. Mr. G. W. Clarke, chief clerk to the committee, stated that the station buildings now in course of erection by Messrs. Macfarlane, of 171, Hornsey-road, are to be completed in accordance with the designs of Mr. A. H. Tiltman, F.R.I.B.A., who has been appointed architect of the work. The contract for the supply of structural iron and steel work has been placed in the hands of Messrs. R. Moreland and Sons, of Old-street. The station, when completed, will cost about £22,000, including white brick facings throughout. The freehold site was purchased from the Great Northern Railway Company, and is situated in the rear of Burnard-place, and comprises about three-fourths of an acre. It is admirably suited to the requirements of the work, a coal siding being constructed on the site, which will enable the necessary fuel to be delivered without extra cost for cartage, a great saving on this head being consequently effected. The Vestry has entered into contracts with Messrs. D. Adamson and Co., of Dukinfield, near Manchester, for the supply of Lancashire boilers, and engines for driving alternators, etc.; with Messrs. Babcock and Wilcox, of 147, Queen Victoria-street, for water-tube boilers; with Messrs. J. Fowler and Co., of Leeds, for alternators, exciters, main switchboard and switches; with Messrs. Elliott Bros., for testing and other instruments; with the British Insulated Wire Company, for street boxes, conduits, etc.; with the India Rubber, Gutta Percha, and Telegraph Works Company, Limited, for cables; and with Messrs. Ferranti, for the arc lighting machinery. Considerable progress has been made in laying the conduits for the cable, about one-third of the compulsory area (which extends from Finsbury Park to the Angel) being covered. The installation is being carried out under the superintendence of Mr. Albert Gay, the Vestry's electrical engineer, who has held the appointments of manager and chief engineer to the House-to-House, the Eastbourne, and the Brighton Companies.

PROVISIONAL PATENTS, 1894.

DECEMBER 17.

24499. **Electric apparatus for conveying and passing currents of electricity, induced, continuous, or currents of high frequency through footboards and oar handles and the bodies of rowers in lifeboats or other boats.** Edmond Savary d'Odiardi and Eva Savary d'Odiardi, 218, Gloucester-terrace, Hyde Park, London.

24500. **Electrodes for conveying different currents of electricity through ladders, trapeziums, wheels, running tracks, dumb-bells, and any other gymnastic apparatus, and through the bodies of those who use them.** Edmond Savary d'Odiardi and Eva Savary d'Odiardi, 218, Gloucester-terrace, Hyde Park, London.

24516. **Improvements in or relating to indicators or telegraphs for hotels, ships, offices, private houses, and for other purposes.** Richard Bowes, 6, Lord-street, Liverpool.

24534. **Velocipedes provided with electrical communicating apparatus.** Raphael Hermann Wolff, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

24541. **Method of and apparatus for effecting electrolysis.** Carl Kellner, 46, Lincoln's-inn-fields, London.

DECEMBER 18.

24551. **Improvements in electricity meters.** Percy Collinson, Sunbridge-chambers, Bradford.

24564. **Improvements in and connected with electro-locomotives.** William Edwin Heys, 70, Market-street, Manchester. (Jean Jacques Heilmann, France.) (Complete specification.)

24583. **Improvements in electric heaters for cars.** George Herbert Whittingham, 52, Chancery-lane, London. (Complete specification.)

24613. **An improved electric signalling system.** William Phillips Hall, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

24625. **Improvements in electric safety appliances for railroads.** Edward Levi Orcutt, 18, Buckingham-street, Strand, London. (Complete specification.)

24630. **Process of and apparatus for dissociating soluble salts by electrolysis.** Henry Spencer Blackmore, 40, Chancery-lane, London. (Complete specification.)

24638. **An improvement in or connected with binding screws for electric conductors.** Rudolf Pelargus, 115, Cannon-street, London.

24639. **Improvements in method and apparatus for purifying liquids magnetically, to which may be added electrolysis and aeration.** John True Harris, 115, Cannon-street, London. (Complete specification.)

DECEMBER 19.

24701. **Improvements in electrically-driven hoists or lifts.** Tangyes, Limited, and Arthur Bryce Mees, 7, Staple-inn, London.

24714. **Improvements in secondary voltaic batteries.** Ludwig Epstein, 28, Southampton-buildings, Chancery-lane, London.

24732. **Improvements in and connected with the reproduction of objects by the aid of the electric current.** Francis Ignatius Ricarde-Seaver and Leon Pernot, 55, Chancery-lane, London.

24738. **Electrical ventilator for ducts, pipes, street boxes, transformer-chambers and other confined spaces used for or in connection with electrical mains and other electrical apparatus.** Ernest Matthew Lacey, 19, Old-Queen street, Westminster.

DECEMBER 20.

24745. **Detachable ornamental fibrous plaster covers for electric light ceiling fittings.** Francis James Curley, 49, Flood-street, Chelsea, London.

24747. **Improvements relating to electric spring connectors.** Leon Harry Cline, Buddle-street, Wallsend-on-Tyne.

24770. **Improvements in and relating to manholes and manhole covers for underground conduits and culverts, transformer-chambers, &c.** George Henry Cottam, the Electricity Works, Hanley, Staffs.

24796. **Improved electric igniting apparatus.** Anton Findenigg and Julius Schwartz, 28, Southampton-buildings, Chancery-lane, London.

DECEMBER 21.

24864. **Improvements in the construction of primary electric batteries in order to make them portable when charged, with improved methods for carrying same, being especially adapted for use on the person, cycles, carriages, and the like kind.** Frederick Arthur George Cassell, Blackhorse-road, Deptford, London.

24873. **Improvements in telephones.** William Phillips Thompson, 6, Lord-street, Liverpool. (The Actien-Gesellschaft für Fernsprechpatente, Germany.)

Digitized by Google

24876. **An improved apparatus for electrically winding up a driving spring.** Hermann Aron, 6, Lord-street, Liverpool.

24899. **An improved dynamometer.** Louis Schuler, 4, South-street, Finsbury, London. (Complete specification.)

24924. **Improvements in telephone switchboard plugs.** James Taylor, Heathercliffe, Helsby, near Warrington.

24926. **Improvements in dynamo-electric machines.** Alexander Bewicke Blackburn and William Buchanan, 47, Lincoln's-inn-fields, London.

DECEMBER 22.

24934. **An improved quick-break or make-time switch.** Henry John Wagg, 2, Adelaide crescent, Hove, Brighton.

24951. **Improvements in safety fuses or cut-outs for electric circuits.** Henry Bleckly Bourne and Walter Fox Bourne, 41, Priory-road, Bedford-park, London.

25014. **Improvements in electrical batteries specially applicable for use in connection with portable electric lamps.** William Herbert and Joseph Herbert, 56, Sanscroft-street, London.

DECEMBER 24.

25031. **Improvements in electricity meters.** George Hookham, 18, Southampton-buildings, Chancery-lane, London.

25066. **Improvements in electromagnetic devices for varying the self-induction of any electric apparatus, also applicable to dynamos and motors.** Llewelyn Birchall Atkinson, 1, Queen Victoria-street, London.

25074. **Process and apparatus for the production of zinc and lead by electrolysis of the melted chlorides.** Richard Ottokar Lorenz, 28, Southampton-buildings, Chancery-lane, London.

25076. **Improvements in or relating to telegraphic transmitters and recording apparatus therefor.** Alfred Julius Boult, 323, High Holborn, London. (Charles Spiro, United States.) (Complete specification.)

25079. **Improvements in or relating to telegraphic transmitters and recording apparatus therefor.** Alfred Julius Boult, 323, High Holborn, London. (Charles Spiro, United States.)

25080. **Improvements in or relating to the separation of metals by electric action.** Thomas T. Oliver, 323, High Holborn, London. (Complete specification.)

DECEMBER 27.

25132. **A method of and means for economically producing electricity.** Jules Célestin Dagoneau, 53, Chancery-lane, London.

25142. **Improvements in the means for fixing electric conductors to walls and other supports.** Hugo Bremer, 433, Strand, London.

25145. **Improvements in the production of copper by electrolysis, and in apparatus employed therein.** John Clayton Mewburn, 55, Chancery-lane, London. (La Société L'Electrolyse, France.)

DECEMBER 28.

25197. **Improvements relating to the charging materials for primary and secondary galvanic elements.** Gustav Platner, 22, Glasshouse-street, Regent-street, London.

25215. **Improvements in electrically-propelled vehicles.** Henry Henry C. Baker and Heber Stone, Times Building, Junction Main and Delaware streets, Kansas City, Mo., U.S.A. (Complete specification.)

25221. **Improvements in dynamo-electric generators and motors.** Llewelyn Birchall Atkinson, 1, Queen Victoria-street, London.

25231. **Incandescent electric lamp gauge.** Robert Dunbar Radcliffe and Charles Lewis Philips, 20, Abchurch-lane, London.

DECEMBER 29.

25263. **An improved arrangement of electric call-bell or alarum.** Remigius Rogg, 166, Fleet-street, London.

25264. **Improvements in electric or galvanic batteries.** Joseph Baxeres Torres, 13, Golden-square, London.

25285. **Improvements in the production of electrical illuminative effects especially applicable for exhibition upon the human body and also for illuminative stage and scenic effects in theatres and the like.** George Frederick Kenyon and Walter Reynolds, 321, High Holborn, London.

25289. **An improved primary battery.** Valdemar Ludvigsen, 4, South-street, Finsbury, London. (Complete specification.)

DECEMBER 31.

25312. **An improvement in the construction of electric arc lamps.** Harry Hewitt and Andrew Casey, 2, North Wharf-road, Paddington, London.

25340. **An improved system of conducters for electrical-decomposing tanks.** John Leith and the Electro-Chemical Company, Limited, 6, Bream's-buildings, Chancery-lane, London.

25344. **Improvements in safety devices for electrical circuits.** Walter Claude Johnson and Louis John Steele, 28, Southampton-buildings, Chancery-lane, London.

NOTES.

Fulham.—The Library Commissioners of the Fulham Vestry have sent us a copy of their seventh annual report (1893-94).

Electric Call System.—It is proposed to establish an electric call system in Brighton in connection with the local post offices.

City and South London Railway.—A writer in a railway journal suggests that this line should be extended to Clapham Junction.

Light Railways.—A paper on this subject by Mr. W. M. Acworth appears in the *Journal* of the Royal Agricultural Society for December.

Church Tower Struck by Lightning.—A few days ago the tower of St. Columb Church, Cornwall, was struck by what is described as a thunderbolt.

Change of Address.—Mr. James Swinburne, of 4, Hatherley-road, Kew Gardens, informs us that he has removed to 66, Victoria-street (2, Princes-mansions), S.W.

Art Furniture Exhibition.—It is intended to hold the third annual exhibition in connection with the above trade in April next, at the Royal Agricultural Hall. The City offices are at 64, Finsbury-pavement, and the manager Mr. G. D. Smith.

Northern Society of Electrical Engineers.—The members of this society will meet on Monday next, the 14th inst., at the Palatine Hotel, Hunt's Bank, Manchester, at 8 p.m. Mr. Henry Edmunds will deliver his presidential address.

Oil-Engine Trials at Cambridge.—The *Journal* of the Royal Agricultural Society contains the report by Prof. D. S. Capper, M.A., of the trials of oil-engines at Cambridge. The report is illustrated, and deals fully with the tests of the various engines tried.

Madras Electric Tramways.—It is stated that this electric tramway, which has been equipped by the Electric Construction Company, was recently set in operation. The system adopted is of the open-conduit type, somewhat similar to the method employed in Budapest.

Matchbox.—By this we do not refer to the racehorse of this name, but to an earthenware matchbox, which has been kindly sent us by the General Electric Company. As the editor does not smoke, he has handed over the matchbox to his assistants for their use—as a paperweight.

Electric Bells.—A new department—namely, the manufacture of electric bells—has recently been added to the business of the Electrical Company, Limited, of 122 and 124, Charing Cross-road, W.C. The company have now issued a price list of the different kinds of electric bells they supply.

Lectures on Dynamo and Transformer Construction.—Commencing with yesterday (Thursday), Mr. James Swinburne began at the Electrical Standardising, Testing, and Training Institution, Faraday House, Charing Cross-road, a series of lectures to the students on "Dynamo and Transformer Construction."

Catalogue of Boilers.—The Cradley Boiler Company, of Cradley Heath, near Birmingham, have sent us a copy of the second edition of their catalogue of boilers. These include those of the Lancashire and Cornish types, horizontal and vertical multitubular boilers, and donkey, semi-portable, locomotive, Galloway, and launch boilers.

Students of the Institution.—A students' meeting of the Institution of Electrical Engineers will be held in the library of the Institution, 28, Victoria-street, on Friday next, the 18th inst., at 8 p.m. A paper will be read on the following subject: "Electrical Transmission of Power (with Special Reference to Mining Operations)."

Trades, Industries, and Arts Exhibition.—It is intended to hold an exhibition at the People's Palace, to be opened in November, 1896, of the arts, trades, industries, and handicrafts existing in the eastern and other industrial districts of London. The hon. secretaries are Messrs. Harold Boulton and Ernest Flower, and the offices are at 64, Cannon-street.

Society of Arts.—On Monday next, at 8 p.m., the first Cantor lecture on "The Arc Light," by Prof. Silvanus P. Thompson, D.Sc., F.R.S., will be delivered. It will deal with the discovery of the electric arc light, early experiments, and the physics of the arc. On Wednesday next, at 8 p.m., a paper will be read on the "Commercial Synthesis of Illuminating Hydrocarbons" by Prof. Vivian B. Lewes.

Electric Motors in France.—A Parisian dealer in sewing-machines in Paris is exhibiting small apparatus showing the utility of electric motors. One of these consists of a sewing-machine driven electrically, one of the best known of the uses of electric motors. The second is an electric churn, in which butter is made in from twenty to thirty minutes. The third is a boot-brushing machine, and the fourth a set of revolving brushes for sweeping the floor.

Behind the Times.—According to our New York contemporaries, the first direct-connected arc light station in the United States was started on December 17 at the Mutual Electric Light and Power Company's plant in Chicago. The new plant consists of a Willans engine connected directly to a 125-light Brush arc dynamo running Brush-Adams lamps. This is stated by our contemporaries to mark a new era in electrical progress. Chicago is behind the times.

Engineering and Machinery Diary. — Messrs. Charles Straker and Sons, Limited, Bishopsgate-avenue, E.C., send us "The Engineering and Machinery Diary," compiled by Mr. J. S. Jeans. In addition to the usual matter in a diary, this compilation contains various formulæ, tables, etc., of an engineering character; a directory of engineers—or, rather, of some engineers, the method of whose selection is not obvious; postal and miscellaneous information.

Code Telegraphy.—The decision arrived at at the last meeting of the International Telegraph Conference (Paris, 1890) resulted in the International Telegraph Office at Berne being entrusted with the duty of preparing a vocabulary of words, for use in code telegrams passing between European countries, to become obligatory three years from the date of publication. This vocabulary has now been issued, containing over 250,000 words, and a copy of it may be inspected on application at the Information Department of the London Chamber of Commerce, Botolph House, Eastcheap, E.C.

Modern Journalism.—On August 3 last we described in our "Notes" an electrically-lighted lifebuoy which had been brought out by the Allgemeine Elektricitäts-Gesellschaft, of Berlin. It took four months for the *Globe* to get this item transferred to its columns, where it appeared early in December. The *Echo*, whose earliness of information must make it a most formidable rival to the other London evening papers, only made the discovery that such an invention existed on Tuesday last. Its comment on the matter is that the buoy should "have a future before it.' It could not well have a future behind it.

Digitized by Google

Casings and Covers.—Promptness is the characteristic of the new price list of electric light cable casings and covers issued by Messrs. McGaw and Co., of York-road, Lambeth, S.E., the list being for January of the present year. It shows a variety of casings both reeded and moulded, and of widths varying from 1¼in. to 5¾in. for the accommodation of ·190 cable and 1·500 cable respectively. There are also "Appendo" mouldings for hanging pictures, but which can also be used as covers for casings.

Temporary Ship-Lighting.—The Caen Chamber of Commerce have had before them the subject of the lighting of vessels passing through the Caen Canal to the sea. A local electric light company has offered to undertake, at its own risk, the electric lighting of the ships, subject to a subsidy from the Chamber of £24 per annum for five years. This has been agreed to. The company engage during that period to have a service of five batteries of accumulators, each with a 200-c.p. projector. They will charge vessels at the following rates: up to 600 tons, £1. 8s.; 600 to 800 tons, £1. 12s.; 800 to 1,000 tons, £1. 16s.; and 1,000 tons and upwards, £2.

African Trans-Continental Telegraph.—A Reuter's message from Cape Town, dated 7th inst., states that the Portuguese have ceased to obstruct the progress of the African trans-continental telegraph, and the line is expected to reach the Zambesi this month. A Central News message from Cape Town, dated 8th inst., announces that the telegraph system of Southern Africa is now working as far as Blantyre. Messages were sent through to that station from Cape Town the previous day. The line would have been opened earlier but for the difficulties thrown in the way by the Portuguese. All these obstacles have now been satisfactorily overcome.

Institution of Engineers and Shipbuilders.—The fourth general meeting of the North-East Coast Institution of Engineers and Shipbuilders will be held in the lecture hall of the Literary and Philosophical Society, Newcastle-upon-Tyne, on Tuesday next, the 15th inst., at 7.30 p.m. The business will include the reply of Mr. A. Young to the discussion on his paper on the "Rolling of Ships"; discussion on Mr. F. Caws's paper "On Ship Acceleration and Fluid Resistance"; and a paper will be read on "The Design and Efficiency of Plant for the Transmission of Power by Electricity," by Mr. W. C. Mountain, member of council.

Royal Meteorological Society.—Two meetings of the society will be held at 25, Great George-street, Westminster, on Wednesday, the 16th inst. The first will be an ordinary meeting for the election of fellows and the transaction of ordinary business, and will commence at 7.30 p.m. At it the following paper will be read: "The Gale of December 21-22, 1894, Over the British Isles," by Mr. Charles Harding, F.R.Met.Soc. At 8.15 p.m., the annual general meeting will commence, when the report of the council will be read, the election of officers and council for the ensuing year will take place, and the president (Mr. R. Inwards, F.R.A.S.) will deliver an address.

Australian Cable Contracts.—It is intended to hold an inter-colonial conference on February 12 to consider the situation created by the decision of the Victorian Government to withdraw from the guarantee given to the Eastern Extension Telegraph Company by all the Australasian colonies except Queensland, and in virtue of which the charges for cable messages were materially reduced. The Postmaster-General expresses the opinion that the colony's withdrawal from participation in the cable subsidy will not render it necessary for the Eastern Extension Telegraph Company to raise the tariff for the transmission of messages to the old figure. Pressure is, however, being brought to bear by New Zealand and the other colonies to induce the Victorian Government to reconsider their decision.

Patents in 1894.—In an article contributed to the *Law Journal* it is stated that the number of patents applied for last year was 25,372, an increase of about 250 over the preceding year. Omitting parts of 100, the figures since 1885 are as follows, the first figure after the date of the year representing applications, and the second the number of successful oppositions: 1886, 17,100, 46; 1887, 18,000, 83; 1888, 19,100, 54; 1889, 21,000, 28; 1890, 21,300, 36; 1891, 22,800, 34; 1892, 24,100, 16; 1893, 25,100, 29; 1894, 25,300, —. As a rule, some 46 per cent. of the total applications are completed, and, although the increase in the number of applications has not been so great in 1894 as in former years, yet it will prove that the number of completed applications will be beyond the average.

English Tramways.—A parliamentary return issued on Wednesday, giving statistics of the various tramway undertakings in the United Kingdom for the year ended June 30 last, shows an increase in every department, more particularly in expenses. The total capital authorised for street and road tramways up to the date named was £17,743,035, being an increase of £813,903 as compared with the previous year. The number of miles of line open had increased by 15, to 975; the number of horses owned by 303, to 30,528; the number of locomotive engines by 1, to 564; the number of cars by 81, to 4,179; and the total number of passengers carried by 18,683,321, to 616,972,830. The gross receipts, it appears, were only augmented by £9,742, to £3,615,837, while the working expenses increased by £21,610, making the net receipts less by £11,868 than for the year 1892-3.

Water Power for Electric Lighting.—Some three and three-quarter miles from Dieppe is the small town of Arques-la-Bataille, which has recently been provided with a central electric light station. The site chosen is at an old mill, 1,100 metres from the centre of the town, and both public and private lighting is carried out. The water power utilised is that of the River Béthune, and the fall of water is 6ft. The old under type of wheel has been replaced by a Hercules turbine of 38 h.p., which, at a normal speed of 77 revolutions, drives by means of gearing a horizontal shaft, the speed of which is 200 revolutions. From this shaft is actuated by means of belt and pulleys a second shaft running at 400 revolutions, and from which the dynamos are operated. The dynamos, of which there are three, are of the Postel-Vinay type, and several hundred lamps are supplied from the station.

Electric Traction in Spain.—A few weeks ago we announced that the Allgemeine Elektricitäts-Gesellschaft, of Berlin, had entered into a contract for the conversion of the Bilbao-Sansurce horse tramway into an electric line. Since that time a company has been formed to work this tramway and another line on the opposite bank of the Ria. It is also intended to substitute electric traction on the latter for the existing system, and negotiations for this purpose are already in progress. The total length of the two tramway systems is approximately 19 miles, and it is intended to operate both lines by means of 28 cars. Of these, 17 will be equipped with two motors of 25 h.p. together, and the remainder with one motor of the same power. In addition to these, there will be eight cars solely used for the transport of merchandise. It is proposed to set the two lines in operation next August.

Digitized by Google

Waterloo and City Railway.—This line is making satisfactory progress. At the staging near Blackfriars two shafts have been driven right down into the London clay, and four great "shields" have been got into position and are being driven across in both directions, two of them burrowing their way along in the direction of the City, and two towards Waterloo. Somewhere about a hundred yards of the tunnel has thus been constructed towards the City, and about half that length in the opposite direction. The rest of the river portion of the work will probably proceed smoothly and rapidly. The work is all through London clay, which is more like a very soft rock that is easily bored. The more difficult part of this undertaking will be met with when the tunnel emerges from under the river on the southern bank. A watery gravel will here be encountered, necessitating a revert to pneumatic pressure as a means of keeping out the water while the tunnels are driven through.

Are Horses Doomed to Disappear?—A representative of a contemporary paid us a visit the other day in great anxiety as to the ultimate fate of horses now that electric traction is coming more prominently to the front. He assured us that during the past five months no less than 5,000 horses which had previously been engaged in tramway working in the United States had been landed at a Scotch port, and that although they were not sent to England, as American cattle sometimes is, as "prime Scotch beef," yet they had a depressing effect upon the prices of horses in this country. We of course expressed sympathy with our friend, who, continuing, asked whether it was possible that electric traction would develop in England proportionately to the same extent as in the United States, and whether electric cars would supersede 'buses, carts, and brewers' wagons. As we are not among the prophets, we had to refrain from predicting the future.

South African Exhibition.—It is proposed to hold a South African exhibition at the Crystal Palace during May-October. The council are satisfied that there exists a sufficient amount of support to warrant the carrying out of the proposed scheme. They recommend to the land, mining, and industrial companies of South Africa, to manufacturers, merchants, and others interested in the trade of that country, the advisability of their being represented at the forthcoming exhibition. The council are satisfied that this exhibition presents a *bonâ fide* opportunity for displaying in a thoroughly genuine and efficient manner the produce and resources of South Africa, and is therefore deserving of the serious consideration and support of all undertakings and persons associated with the trade of that country. It has been determined to defer the allotment of space till the end of January, by which time it is hoped that intending exhibitors will have sent in their applications to the Crystal Palace Company.

Electric Lighting in France.—It has been decided to erect a central electric light station at Cazères, Haute-Garonne.—The Luneville Municipality have made an agreement with Madame Jeanmaire for the electric lighting of the town.—A petition has been presented to the Marseilles Municipality for an extension of the electric light mains.—Messrs. Passot and Vergnes have applied to the Municipality of Morez for a concession for a central electricity station in that town. The Municipality of Cambrai, Nord, want tenders for the gas and electric lighting of the town.—The village of Montbozen, Haute-Saône, has only between 500 and 600 inhabitants, but a central electric light station has been completed there.—Messrs. Laroudie and Co. are desirous of obtaining authority to establish a central electricity station and an electric tramway at Périgueux.—A concession has been granted to Mr. Emilien Beaufumé for the establishment of a central station at Vermonton, Youne, a town of 2,000 inhabitants.

Electric Flash-Lights.—The scene of disembarkation of the passengers on the "Empress," which was run aground a few days ago at Calais, was sufficiently picturesque. It was dominated, a correspondent states, by the splendid light of the Calais Lighthouse, with its relentless four flashes and a pause, lighting up the dark ramparts of the fortifications and the belt of smooth wet sands fringed by the white foam of the breakers, and throwing into relief black heaps of wreckage which had drifted from the pier. At the foot of the ladder was collected a noisy mob of excited Frenchmen with two or three lanterns, ruddy in contrast with the electric light. The wind was very high and splashed a sleety rain in passengers' faces. But it must be said that, for healthy persons at least, there was no serious difficulty, or even inconvenience. By half-past 10 the passengers were ashore with their hand baggage, and on the whole the experience may be described as a shipwreck made easy.

Danger of Welsbach Lights.—The following is given by the New York *Electrical Review*: "'Those Welsbach gaslights made a good deal of trouble in my family,' observed a prosperous merchant. 'In my library I have a gas-jet set low down over a couch on which I lie and read. I can't get current into my house, so I have to do as well as I can with gas. Hearing of the Welsbach light, I ordered my gas-man to put one on my reading light over the couch. The other evening I was lying reading, when, as I often do, I fell asleep. The family was out, and when they returned I was still asleep, and the Welsbach was burning full tilt. I was awakened by a chorus of screams and sobs. My wife and the girls thought I was dead. That ghastly green tinge peculiar to the Welsbach light had cast its effulgence over my countenance, and my wife said I looked exactly like a corpse. The Welsbach is gone, and I have resumed using the old gas-burner, while patiently waiting for the electric current to be supplied in my street.'"

Electric Lighting for River Steamers.—An Indian contemporary observes: All the steamers belonging to the Rivers Steam Navigation Company and the India General Company are to be fitted up with electric light so as to enable them to trail down the rivers at night. The prohibition to travel by night has been a crying grievance with the mercantile community ever since the water highways of Eastern Bengal have been overrun by steamers conveying jute, tea, and other valuable cargo to Calcutta. The rivers there are mostly broad and deep, but they are studded with shoals and sandbanks which are a standing menace to vessels travelling at night. No commander dare pursue his journey after regulation hours even with the help of a bright moon. If the above proposals are carried out it will cut short the passage considerably and greatly benefit all parties concerned. In the case of jute, the risk of the cargo catching fire will be greatly minimised, and as regards tea, it will go far towards putting an end to the bitter complaints which are constantly being heard on account of the great delays and loss occasioned to shippers under the present system.

Personal.—Mr. Stephen Sellon informs us that he has resigned his appointment with the Electric Construction Company, Limited.—Mr. W. J. Furse, electrical engineer, of Nottingham, has been elected chairman of the West Bridgford District Council. This appointment carries with it a seat on the magistrates' bench for the county of Nottingham.—Mr. A. H. Bayes has been appointed electrician to the Brymbo Iron and Steel Company, Brymbo,

Digitized by Google

near Wrexham.—Mr. J. S. Cunnington, who has been for over 10 years chief electrical engineer and manager of the electrical department of Messrs. B. Verity and Sons, Covent-garden, has severed his connection with them.—Mr. Henry Eaton, the late superintending engineer of the metropolitan district of the Postal Telegraph Department, has been presented by his former colleagues with a handsome testimonial as a mark of their esteem. Mr. W. H. Preece, C.B, F.R.S., engineer-in-chief of the department, acted as the spokesman of the subscribers.—The council of the Institution of Civil Engineers have transferred Mr. W. B. Esson to the class of member, and Mr. J. S. Raworth has been elected a member.—The *Electrical World* of December 29 contains a portrait and biographical sketch of Mr. Gisbert Kapp.

The Fecamp Central Station.—A description is given in *L'Electricien* of December 22 and 29 of the central station erected at Fécamp, a French town having a population of 14,000 inhabitants. The plant, which was originally contained in a sawmill, at first comprised two Edison dynamos, giving 80 amperes at 115 volts, driven from a countershaft in the mill. As the demand for light increased, a battery of Laurent-Cely accumulators was installed, 700 metres from the generating plant, so as to provide an additional supply. As, however, the number of consumers increased, it was decided to erect new works on the site of an old mill in the Place de l'Hotel de Ville, where a 25-h.p. turbine was in operation. The new station contains two De Naeyer boilers and two Weyher and Richemond vertical engines, each of 85 h.p. and running at a speed of 200 revolutions a minute. In addition to these, there is a Hercules turbine, which by means of gearing drives two Edison dynamos each giving 80 amperes at 110 volts. The voltage of these two machines can be raised to 150 volts for the purpose of charging accumulators. The two steam-engines actuate two dynamos, giving 220 amperes at 125 volts. There are four sets of accumulators, each battery comprising 69 cells. Some 2,000 lamps are connected to the distributing mains.

Telephony Between Trains and Railway Stations.—A correspondent of the *New South Wales Railway Budget*, writing from New Zealand in reference to the Wellington and Manawater Railway, says: "Some interesting experiments have been made on this railway by Mr. Fulton, the engineer to the company, as to the feasibility of intercepting the telephone currents along the line in order that the guard of the train may be able to establish communication with any of the stations or with the head office in case of accident or delay to the trains anywhere upon the line. The company possesses a telephone wire running beside its line along its whole length with instruments at each station. A telephone instrument has been fitted in one of the guards' vans, and attached to it is a reel of wire, upon one end of which is an iron hook. Wherever the train may stop the guard has merely to run out his reel, and throw the hook over the permanent telephone wire, and he is immediately placed in communication with the whole of the stations and the head office, the divided current being sufficiently strong to carry both ways, and the wheels of the van and the rails contributing the necessary earth connection. For instance, the train can stop a mile from Wellington, and the guard there throws his hook over the wire, when he can be heard either in Wellington or at Longburn, and at every station between."

Internal Conduit System of Wiring.—The system of placing lighting leads in wooden mouldings in the United States in the early days resulted in a number of fires, and attention was therefore directed to the introduction of an improved system. Such a method was brought out some five years ago by the Interior Conduit and Insulation Company, of New York, of which Mr. E. H. Johnson is the president. This system, which has now become practically universal in the United States, is about to be introduced in this country by Mr. Fred Bathurst, who for the past four years has been connected with the Edison Electric Company in America, and who has just returned home. The system consists in the use of iron piping having an inner tube of asphaltic compound with paper as the base, and through which the leads are passed and readily drawn out at any time. In fact, it may be said to be the use for internal work of the underground pipe system laid in the streets for cables, together with their junction-boxes. Mr. Bathurst, who hopes to bring the merits of the system before English wiring contractors, has not yet completed his office arrangements, but enquiries may be made to his private address, 14, Greencroft-gardens, South Hampstead, N.W. We must not omit to mention that this system has already been successfully developed in Germany by Messrs. S. Bergmann and Co., of Berlin, and it is said to be rapidly becoming acknowledged in that country as the standard method of electric wiring.

Electric Lighting in Germany.—A central station has been opened at Aibling.—A mill owner at Münster proposes to use his superfluous water power for supplying current to Gaildorf, about a mile distant.—An agitation is taking place against the proposal of the Goslar municipality to establish municipal gasworks. A petition has been numerously signed against the scheme, and the authorities are being asked either to establish a central electricity station or to go on with petroleum lighting as in the past. Sixty local firms have also signed an undertaking that if a gasworks be established, they will not take any gas.—An electric lighting company is negotiating for the purchase of water power at Fraulautern to erect a central electric light station.—The new Adler Hotel, which is being built at Schönwald, in the Black Forest, is to be lighted electrically. Now other hotel-keepers, as well as manufacturers and shopkeepers, have announced their intention of adopting the new illuminant.—The Allgemeine Elektricitäts-Gesellschaft, who are preparing for the erection of a large central electric light station at Oberschönweide on the Upper Spree, propose to light various villages in the district from Treptow to Köpenick and Friederischshagen, and also to supply them with current for power purposes.—It is intended to have an electric light installation in connection with the large Rangir railway station at Nuremberg which is being erected.—Messrs. Schuckert and Co. have arranged for the establishment of a central electric light station at Goldberg.—It is proposed to establish a municipal electric station at Mayence.—Messrs. Heinrich Taaks and Co., of Stuttgart, have completed a central station for the Offenburg Colliery Company at the Berghaupten pit. Alternating current at 3,000 volts is employed and transmitted to the town of Gegenbach, Kinzigthall, a distance of three and a half miles.—Various places in the Palatinate—such as Bergzabern, Wachenheim, and Haardt—have introduced the electric light.—A project has been mooted for the electric lighting of Elmstem. Water power is available.

Gas Batteries. — An abstract is published in the *Journal* of the Chemical Society of a paper contributed by Mr. F. J. Smale to the *Zeit. Physikal Chem.* on "Gas Batteries." The E.M.F. was determined in the case of a large number of gas batteries, the electrode being usually platinum strips coated with platinum black, and immersed partly in the gas, partly in the electrolyte. Experiments were performed to test the dependence of the E.M.F. on the

Digitized by Google

nature and size of the plates and nature and concentration of the solutions. The nature of the plates had no effect, similar results being obtained with gold, platinum, and palladium, whilst a slight variation with the size in the case of an oxygen-hydrogen chain is explained by the slight absorption of oxygen by platinum black. The E.M.F. appeared to be independent of the electrolyte and its concentration, in the case of sulphuric, phosphoric, and chloracetic acids, and also, although less certainly, with sodium and potassium hydroxides, sodium sulphate, and potassium chloride. Abnormal values were, however, obtained with the halogen acids and many salts, which the author accounts for by the existence of secondary actions. Gaseous chains of hydrogen chlorine, hydrogen bromine, and hydrogen iodine were investigated, and the effect of dilution of a gas studied by the comparison of a hydrogen-oxygen with a hydrogen air chain, the E.M.F. in the latter case being about 10 per cent. lower. The means of the result for the chains are: hydrogen oxygen, 1·044 volts; hydrogen chlorine, 1·532 volts; hydrogen bromine, 1·111 volts; hydrogen iodine, 0·530 volt. By immersing the electrodes in the same electrolyte at different concentrations, the E.M.F. between the two solutions is found, and a number of tables with these results are recorded. The E.M.F. in the oxygen-hydrogen chain falls regularly as the temperature increases, thus: 0deg. = 1·090 volts, 20deg. = 1·065, 40deg. = 1·033, 60deg. = 1·001; and from these numbers the temperature coefficient of the solution tension is calculable, giving the result $\frac{d\pi}{dt} = -0{\cdot}00140$—that is, the solution tension is inversely proportional to the absolute temperature. The E.M.F. with the similar electrode in an electrolyte at different temperatures was also observed and calculated, with fair agreement in the results.

The Heilmann System of Electric Traction.—A correspondent recently informed *L'Energie Electrique* that he had never yet been able to travel in a train hauled by the Heilmann electric locomotive, which we described early last year. That journal now publishes in its issue of the 1st inst. a copy of a remarkable circular issued by the administrative council of the company working this system. After referring to the experiments with the locomotive on the lines of the Compagnie de l'Ouest, the circular states that after trials extending over from eight to ten months, the first locomotive was put out of service. This is stated not to be due to lack of success. On the contrary, the railway company considered the results to be so satisfactory that they agreed to rent two new locomotives, but the company could not establish a regular service with a single locomotive. As a means of utilising this first locomotive, it is suggested that it might be made to serve as a central station, and that the four-wheeled bogies could be used for hauling purposes, the current to be supplied by an overhead conductor. With regard to the two new locomotives, it is mentioned that they will be of 1,500 h.p. each, capable of hauling from 200 to 250 tons at a speed of 62 miles an hour. The construction is being rapidly pushed on so that the locomotives may be placed at the disposal of the company during the present year. The contract for the supply of the boilers, bogies, and water-tanks has been placed with the Société des Anciens Etablissements Cail, that for the dynamos with Messrs. Brown, Boveri, and Co., and that for the steam-engines with Messrs. Willans and Robinson, of Thames Ditton. All these steps have been taken with the assistance of the railway company, to whose specification the contractors are working. At the time of entering into these contracts, the circular proceeds, the Heilmann Company took the opportunity of granting to Messrs. Brown, Boveri, and Co., for Switzerland, Germany, and Italy, and to Messrs. Willans and Robinson, for England, India, and the British colonies, the exclusive right of working the Heilmann patents in those countries respectively. The company, in addition to these patents, possesses others relating to navigation and to self-contained cars on rails and on roads, but it is crippled for want of capital. A means of raising fresh capital, the circular concludes, is now under consideration.

Electric Ploughing Experiments.—Some experiments in the direction of driving ploughs by electric motors have recently been made by Messrs. F. Zimmerman and Co., of Halle. The company have introduced a new kind of plough, which is illustrated and described in the New York *Electrical Engineer* of the 26th December. It appears that the plough is not pulled over the ground at the end of a wire rope, but the electric motor is mounted on the tipping plough and is carried with the plough as the latter is drawn over the field. The armature of the motor, through the medium of a chain and sprocket wheel, drives the shaft, over which passes a chain stretched along the length of the field. Both ends of this chain are fastened down securely by triple anchors. When the motor is set in operation it winds the plough over the field on the stationary chain. At the end of the field the plough is tipped and by a simple switch the motor is reversed and pulls the plough in the other direction, at the same time laying the chain sidewise for the next furrow to be ploughed. The shifting of the anchors is done by means of a crowbar, which pulls the anchor out of the ground, and the anchors are mounted on wheels so that they can be easily moved. No trouble, of course, is encountered in the operation of the plough as just described, but the drawback which has always stood in the way of the application of electricity to ploughing has been the difficulty of conducting the current to the motor with the plough travelling over the field. The usual method of conducting current to a moving motor by means of trolleys in contact with a fixed conductor was evidently out of the question here. The manner in which this important point has been provided for is exceedingly interesting. Since the plough passes to and fro for a comparatively short distance, it may be considered as the end of a pendulum bob, which is connected to the centre of oscillation by the connecting cable, so that the latter, vibrating over the field, follows the movement of the plough. In order to avoid the friction and wear on the cable as it passes over the ground, the cables are mounted on light rollers and held by clamps, the rollers following readily the direction of motion of the plough. Up to the present time the company has built two ploughs, one with two shares and one with four, both of which were put in operation in the neighbourhood of Halle. The results were most encouraging, from the standpoint both of the quality of the work and the power consumed. The two-share plough was driven by current obtained from a dynamo driven by a 10-h.p. portable engine. The earth was a heavy binding clay. The dynamo gave 110 volts and 60 to 80 amperes on an average, which would be equivalent to about 12 h.p. delivered by the engine. The plough made two furrows having a combined width of 60 centimetres and a depth of 24 centimetres. The spring dynamometer showed a pull of between 600 and 700 kilogrammes and an average of 650 kilogrammes, which would give a resistance of 49·2 kilogrammes per square decimetre of furrow cross-section. When the plough was driven at the rate of ·9 metre per second, 8 h.p. was consumed, showing a loss of 4 h.p. between the portable engine and the plough. Compared with the indirect steam plough, this was a very small loss.

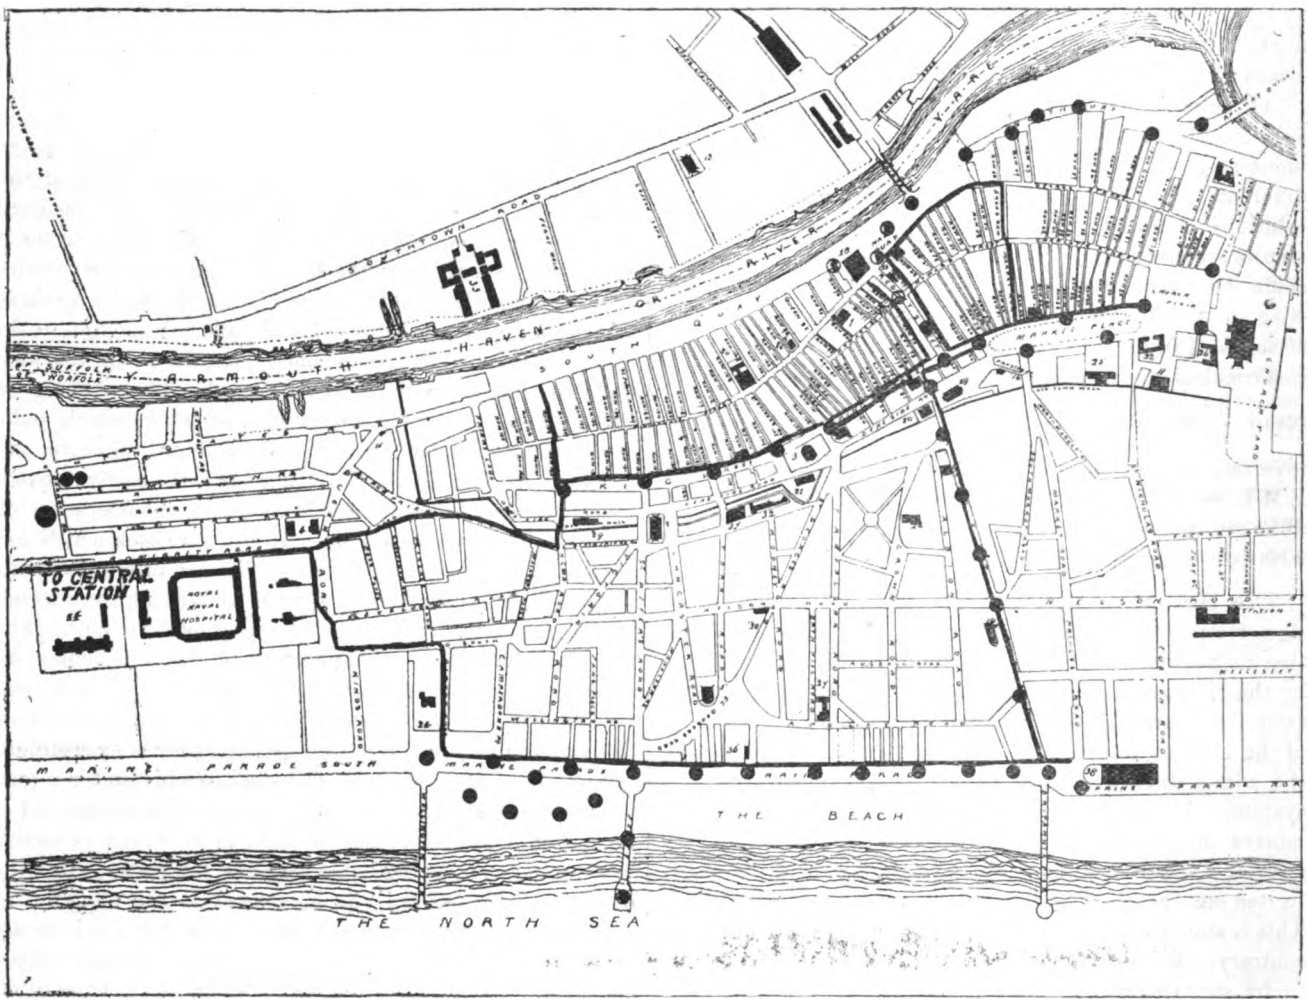
THE ELECTRICITY WORKS AT YARMOUTH.

The Town.

A favourite and attractive watering-place during the season, but dull and dreary in winter time, are the conclusions arrived at by the occasional visitor in regard to what is sometimes termed "bloater land." Yarmouth, it is scarcely necessary to mention, derives its name from the fact that it is situated at the mouth of the Yare, about 20 miles from Norwich; and its population comprises some 50,000 inhabitants, this number including those persons living on the other side of the river in Gorleston and Southtown, which form part of the borough. The latter covers an area of 4,500 acres.



Yarmouth.—Map Showing in Black Lines the Position of the High and Low Pressure Cables, and in Black Dots the Arc Lamps.

The Municipal Buildings, which were erected in Hall Quay in 1882, are of a handsome character. It is from Hall Quay that the steamers of the General Steam Navigation Company convey passengers daily during the summer to and from London. Close by are the North and South Quays. The latter is of most interest to visitors, as an agreeable promenade is afforded by an avenue of trees arranged parallel for a long distance. Vessels from different parts of the Continent and from the North of England may be seen here, unloading ice for the fishing trade, and coal, timber, corn, etc. Yarmouth is one of the largest stations belonging to the Trinity Service, and no less than 12 lightships are stationed off this dangerous coast. Passing along the Marine-parade, which fronts the beach—a lively place in the season—one comes to the promenade, the South Denes. This is known as the race-course, and is about a mile and a half in length, and being flat allows of grand field days of the volunteers being held in the summer.

An interesting and historic landmark is afforded by St. Nicholas s Church, which was originally founded in 1101, and which is said to be the largest parish church in this country. There are numerous other churches, chapels, and educational institutions. Of the places of amusement may be mentioned the New Theatre Royal and the Aquarium.

Preliminary Steps in Electric Lighting.

It cannot be said that the Corporation of Yarmouth have made undue haste in establishing municipal electricity works. It is doubtful whether the undertaking now on the point of being inaugurated would have reached this stage, or, at all events, at the present time, if it had not been for the exertions of Mr. J. W. Cockrill, A.R.I.B.A., A.M.I.C.E., the borough surveyor. As long ago as in 1889 Mr. Cockrill presented a report to the Electric Lighting Committee, and in August, 1890, the provisional order issued to the Corporation was confirmed by the Electric Lighting Orders Confirmation (No. 6) Act, 1890. A year subsequently the borough surveyor recommended that information should be obtained as to the number of persons willing to guarantee taking a supply; that an advertisement to that effect should be inserted in local papers; that the latest information, in a tabulated form, should be procured from each town in which electric lighting had been introduced; that the borough accountant should obtain information as to the financial results which had attended the working of electric light enterprises; and that a sub-committee should be empowered to visit some towns and inspect the various systems at work.

These recommendations were adopted by the Corporation, and the borough surveyor was authorised to obtain further particulars on the subject of electric lighting. Shortly afterwards Mr. Cockrill was enabled to place before the Electric Lighting Committee an admirable tabulated

Digitized by Google

statement prepared from the information furnished, we are pleased to say, with their characteristic courtesy, by no less than 97 borough engineers and surveyors. Beyond stating that this report has formed the basis of other and similar statements, it will be unnecessary to enter further into the matter on this occasion. At the same time it unfortunately happened that the result of the local advertisements for consumers was the promise of the insignificant number of less than 200 lamps!

In the meantime the sub-committee appointed according to the above recommendation, and consisting of Messrs. F. Danby Palmer (chairman), R. Martins, H. Harvey-George, J. H. Bly, and J. W. Cockrill (borough surveyor), were making investigations. They visited the works of Messrs. Crompton and Co., the St. Pancras station, the works of Messrs. Ferranti and of the Brush Electrical Engineering Company, and the stations at Chelsea, Manchester-square, Kensington Court, and at Bradford. As a result of their personal examination, the sub-committee recommended the adoption by the Corporation of the high-pressure alternating-current system, with sub-stations, and that the borough surveyor should prepare plans and specifications for the carrying out of the undertaking.

Tenders were received from six companies, but for some reason or other not one of the offers was accepted, and the matter remained practically in abeyance for some months. In the interim the Local Government Board sanctioned a loan of £15,000 for establishing municipal electricity works. Eventually fresh tenders for the buildings and plant were invited, this being in January, 1894, and Mr. W. H. Preece, C.B., F.R.S., was called in to advise the Corporation on them. As a result the tenders of Messrs. Crompton and Co., Limited, of Mansion House-buildings, London, E.C., and of Chelmsford, for the supply and erection of the whole of the plant, and of Messrs. J. F. W. Bray, of Yarmouth, for the erection of the station buildings, were accepted.

The Adopted System.

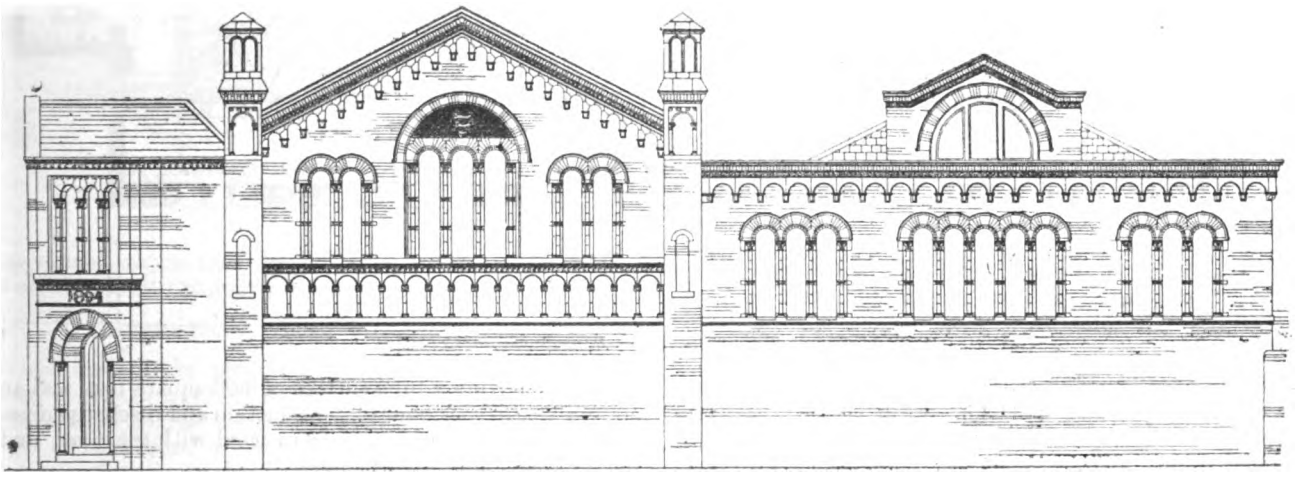
As far as the system adopted is concerned, it comprises high-pressure alternating-current generators with transformer stations for incandescent lighting, and direct-current series machines for street illumination by means of arc lamps. As will be seen from the map, the town is of a straggling character, with a portion of the borough on each side of the river.

Naturally enough, with the provisional order covering the whole borough as the authorised area of supply, and with the decision of the Corporation to erect the station outside the town where water for condensing purposes could be easily obtained, and the cost of cartage of coal saved, there was no alternative than to adopt the alternating-current system. In fact, although the compulsory area only includes the west side of the Market-place, King-street from Market-place to Row 131, Regent-street, Market-row, Broad-row, and Hall Quay, the system laid down is, taking everything into consideration, the best adapted to the requirements of the town. But it will be observed from the dots on the map, which represent the positions of the arc lamps, that the Corporation have already commenced street-lighting outside the compulsory area.

It was originally intended to start the supply to private consumers in September last, but in consequence of some delays the opening of the station is only now about to take place. The arc lighting, it may be mentioned, was commenced in August. The site chosen for the station is Corporation land in the South Denes-road, about 1½ miles from the Hall Quay, or centre of the town. Here supplies of coal are readily obtainable, whilst water

Yarmouth.—North Elevation of Station

North Elevation



Yarmouth.—West Elevation of Station.

Digitized by Google

for condensing purposes is obtained from the river adjoining.

The names of the present members of the Electric Lighting Committee are given below, the Mayor being Mr. F. Arnold.

ELECTRIC LIGHTING COMMITTEE.

MR. RICHARD MARTINS (CHAIRMAN), DEPUTY MAYOR.

MR. J. H. BLY.	MR. J. H. PALMER.
MR. F. BURTON.	MR. W. H. PALMER.
MR. W. H. CROME.	MR. F. DANBY PALMER.
MR. E. A. DURRANT.	MR. B. HOWARD PRESS.
MR. T. GOATE.	MR. T. SAUL.
MR. E. J. HART.	MR. A. STANLEY.
MR. J. W. BUDDS JOHNSON.	MR NORFORD SUFFLING.
MR. R. NUDD.	MR. E. WINTON.
MR. J. RUNNIFF NUTMAN.	MR. E. W. WORLLEDGE.

An idea of the general arrangement of the station, which is capable of being considerably extended, will be gathered from the plan and cross-section, whilst the buildings are shown in elevation.

The Boiler-House.

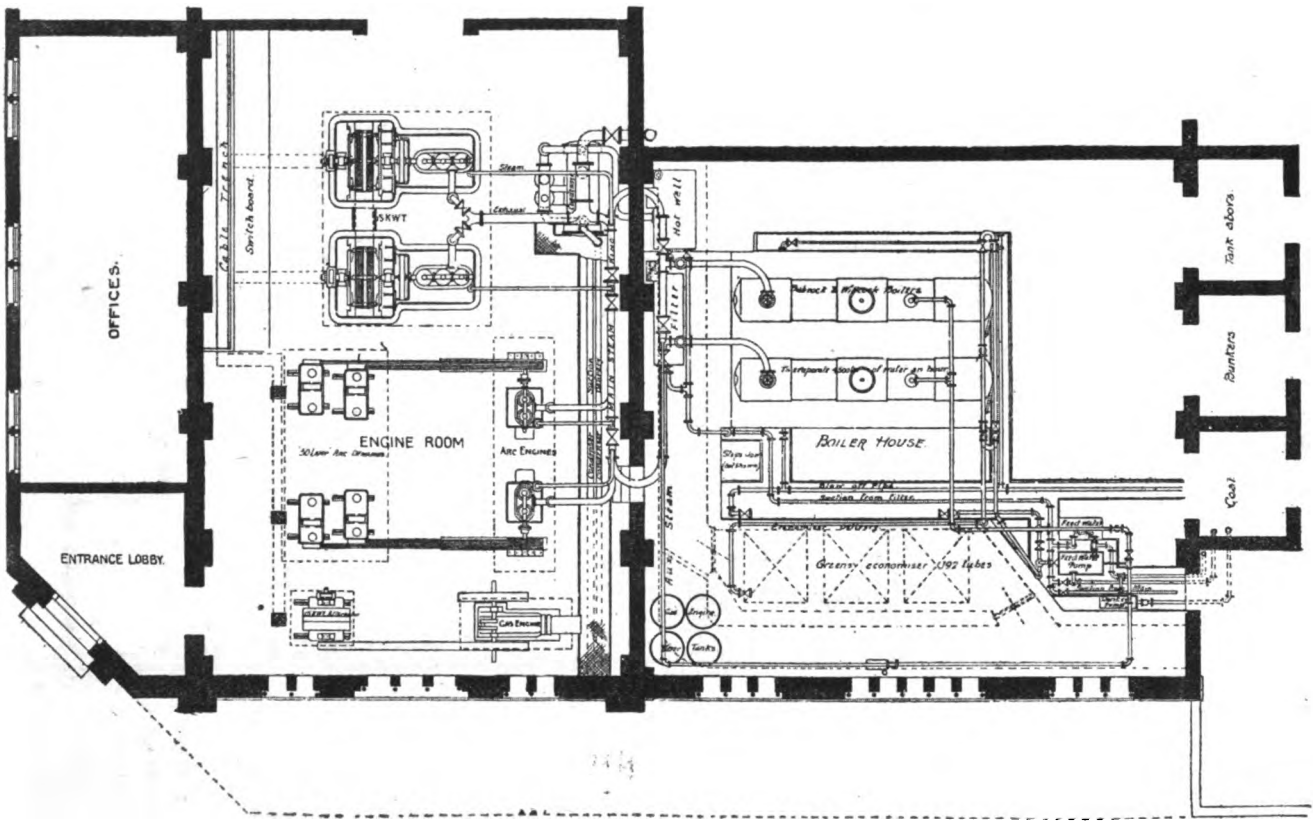
The boiler-house, which is arranged 4ft. 6in. below the level of the engine and dynamo room, contains two water-tube boilers of the Babcock and Wilcox type, constructed for a working pressure of 150lb. Each boiler is capable, with the feed water at 60deg. F., of evaporating 4,500lb. of water per hour. These boilers are provided with a feed-water ring main 3in. in diameter, and with a duplicate feed to each boiler, so that the pumps can supply either one or both boilers, and the security of the feed is effected.

There are two feed pumps of the Worthington duplex type, each capable of delivering 2,500 gallons of water per hour, and made by the Worthington Pumping Engine Company, of Queen Victoria-street, E.C. Outside the station are arranged two water-tanks having a total capacity of 9,000 gallons. These tanks are filled from the town mains by means of a donkey pump made by Messrs. W. H. Bailey and Co., of Salford, and the water is drawn from them by the pumps.

The general plan clearly shows the arrangement of the steam and exhaust pipes. It will be seen that the ring system, which has met with considerable favour in central-station work, has been introduced, together with an auxiliary steam ring main for use when necessary. The boilers deliver from their connecting pipes into the main steam ring, which is carried through the wall of the boiler-house into the engine-room, and from there the branch pipes are taken off to the engines. The ring main is of wrought iron 6in. in diameter, and the bends and branches to the engines are of copper. It will be noticed that the arrangement of the main steaming and auxiliary steam main, together with the valves, is such that the contingency of a breakdown of one boiler or a portion of the ring main would only disable that particular boiler and one engine. Separate pipes are taken to the condenser and for the operation of the pumps. Suitable arrangements are provided for draining the sections of the steam main and the engines.

The main exhaust-pipe, which is of cast iron, is 12in. in diameter, and is normally connected direct to the condenser. When the latter is not at work the exhaust steam is allowed to pass into the atmosphere through a 10in. pipe, as indicated on the plan. When, however, the condenser is in operation the valves between the exhaust-main and the exhaust-pipe to atmosphere are closed, and the condensed steam from the engines and condenser passes into the hot-well, as shown.

The condensing plant, which has been made by Messrs. W. H. Allen and Co., of Bedford, comprises a surface condenser having a tube surface of 600 square feet, and an air and circulating pump. The suction and discharge pipes of the circulating pump are connected with the river, and the air-pump with the condenser.



Yarmouth.—Plan Showing the General Arrangement of the Station.

To remove the oil gathered in the engines, the water from the hot-well is passed into a filter, from which it is drawn by either of the pumps, or, if necessary, the filter can be disconnected. The water is then either pumped into the boilers direct or is forced through the tubes of an economiser, supplied by Messrs. E. Green and Son, Limited, of 2, Exchange-street, Manchester, and thence passed into the feed-water ring main. This economiser consists of 192 tubes arranged in two groups fitted with expansion elbows, and provided with space between the pipes and the wall, thus facilitating examination, and giving access to all parts. The machine is constructed from new patterns to withstand the boiler pressure of 150lb. per square inch, all portions subjected to internal pressure being considerably strengthened.

Day-Load Plant.

As in the case of Bristol and Bedford, and as is now being specified for other towns, so also at Yarmouth has a gas-engine alternator been erected for dealing economically

Digitized by Google

with the demand for light on the part of private consumers during the day and late at night, when the lighting requirements do not necessitate the continued working of the large machines. In this case the method of driving is by means of belt.

The gas-engine is of the Crossley type, capable of indicating 33 h.p., running at 200 revolutions, and driving, by means of a belt, a 15-kilowatt Crompton-Brunton alternator direct coupled to its exciter. The engine is fitted with heavy flywheels and special governor so as to ensure steady driving, and the alternator gives 7·5 amperes at 2,100 volts.

Arc Lighting Plant.

As will be seen from the plan showing the general arrangement of the plant, there are two sets of arc light machinery. Each set comprises an engine driving two dynamos set back-to-back, an arrangement which appears to have been more used on the Continent than in this country.

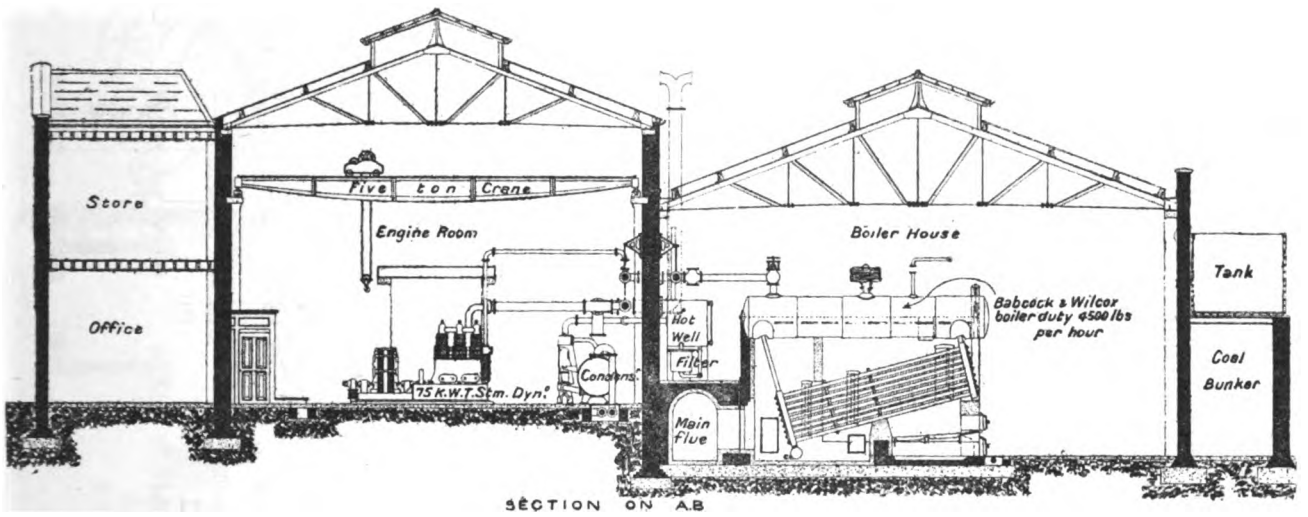
These engines are of the Willans F F compound type, arranged with independent outer plummer-boxes and pulleys for driving the arc light dynamos by means of ropes. The diameter of the high-pressure cylinder is 8½in. and of the low-pressure cylinder 12in., the stroke being 6in. Each engine has two cranks, with a low-pressure and high-pressure cylinder placed tandem fashion over each crank. The engines, which run at 450 revolutions a minute, each actuate two arc machines, the speed of which is 830 revolutions. These dynamos are of the Crompton type, being provided for this purpose. The two exciters, which, as already mentioned, are direct coupled to an extension of the armature shaft, each yield 24 amperes at 65 volts.

The engine and dynamo room is equipped with a five-ton overhead travelling crane, made by Messrs. Isles, Limited, of Stanningley, near Leeds. It is of the company's ordinary type, and is capable of lifting loads of five tons. The cross girders are of rolled steel, and the span is 35ft. The end carriages are made of wrought iron, with flanged tram wheels. The crane has motions for hoisting and lowering, two speeds, and for travelling longitudinally and transversely. All the motions are worked from the floor by endless ropes passing over grooved pulleys, and a brake and pawl are attached to the crane.

The switchboard, which is arranged on one side of the engine and dynamo room, is built up of slate panels, and of Messrs. Crompton's usual type. A separate panel is provided for each alternator, each feeder circuit, and each exciter circuit, and one is arranged for the synchroniser and pilot-wire voltmeters. Spare panels are available for additional machines. The usual arrangements for the arc light circuits have been adopted.

The Feeder and Distributing Mains.

The work of supplying and laying the mains, boxes, and connections was entrusted to the British Insulated Wire Company, Limited, of Prescot. We are able to give cross-sections of the high-pressure feeders and arc light cables.



Yarmouth.—Cross-section Through the Station.

series wound, and as each gives 10 amperes at 1,590 volts, it is capable of energising 30 2,000 c.p. lamps.

Incandescent Lighting Plant.

In the case of the plant for incandescent lighting, the method of direct driving has been adopted for the triple combination of engine, alternator, and exciter, as indicated on the general plan of engines and alternators and in elevation. There are two such combinations, and the periodicity of the alternators, which are, of course, arranged for parallel working, is 83·5 per second.

The engines are of the Willans G G G S compound type, arranged upon special bases. Each engine is bolted directly up to the bedplate of a Crompton-Brunton alternator, to the spindle of which it is rigidly coupled. The speed of each engine is 460 revolutions per minute, and each is capable of developing from 130 to 140 effective horse-power. The stroke is 6in., and the diameter of the high-pressure cylinder is 10in. and of the low-pressure 14in. Each engine has three cranks at 120deg., and as each crank has a complete compound engine driving it, the turning moment is very even, being the same on each crank at any load. This is a matter of considerable importance in running alternators in parallel.

The Crompton-Brunton alternators, each of which gives 36 amperes at 2,100 volts, have revolving disc armatures, the coils of which can readily be replaced at any time that occasion may arise. The lubricating arrangements are very efficient, a small pump driven by belt from the shaft

Paper-insulated and lead-covered cables are used throughout, the mains being armoured with steel strip, and laid direct in the ground.

The section marked A is a high-pressure cable $^{6}/_{9}$'s in the core, with a pilot wire in the centre and one on the outers of cables; B is a $^{19}/_{18}$ double concentric high-pressure cable; and C is a section of the arc light $^{7}/_{16}$ high-pressure single cable, of which nearly ten miles have been supplied. All these cables were tested to 10,000 volts before being sent from the works, and were tested to 4,000 volts at Yarmouth last week.

The low-pressure distributing mains are twin armoured cables, ·1in. square section, and each house-box is made to serve two consumers. These mains were subjected to a pressure of 5,000 volts when connected.

At present there are two arc light circuits taken from the station to the arc lamps in the town. In addition to this, an alternating circuit is provided for energising some alternating-current arc lamps.

There are two feeder mains for the incandescent lighting, which are taken to four transformer-chambers built under the pavement. Two of these sub-stations each contain a Crompton transformer of 25 kilowatts capacity, space being available for the accommodation of an additional converter of the same output. In each of the other two sub-stations is arranged a 15-kilowatt transformer of the same type, there being spare room also in this case. The reduction is from 2,000 volts to 102 volts, at which pressure the electrical energy is supplied to consumers.

Digitized by Google

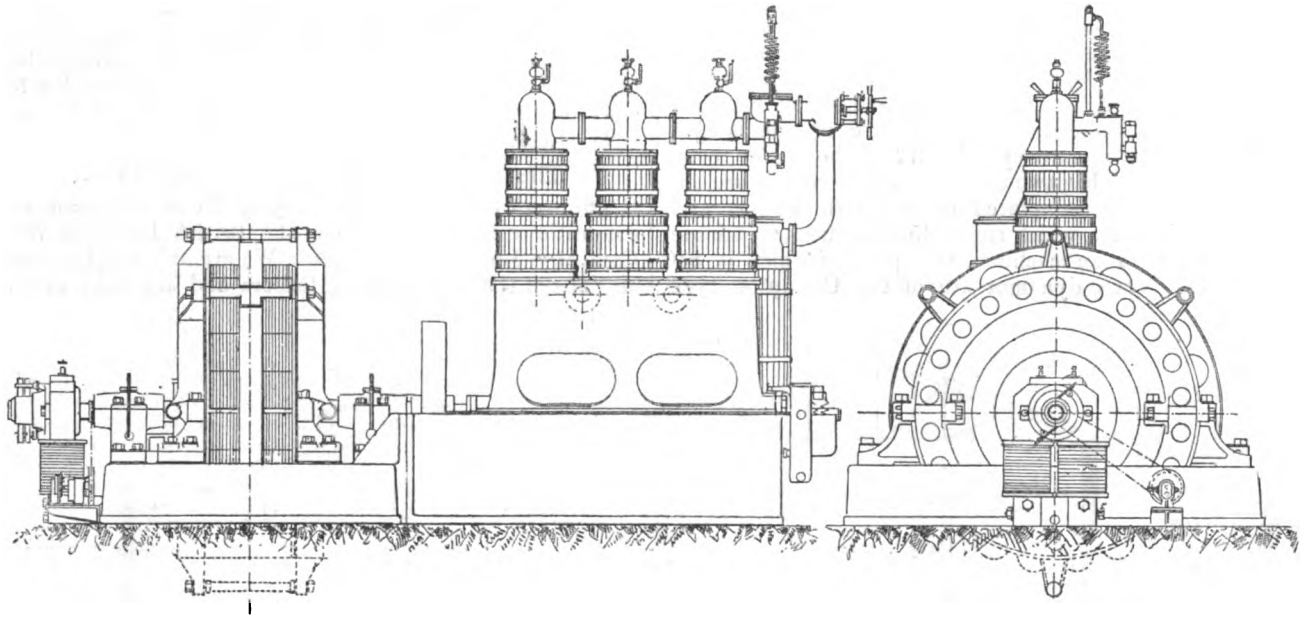
Public and Private Lighting.

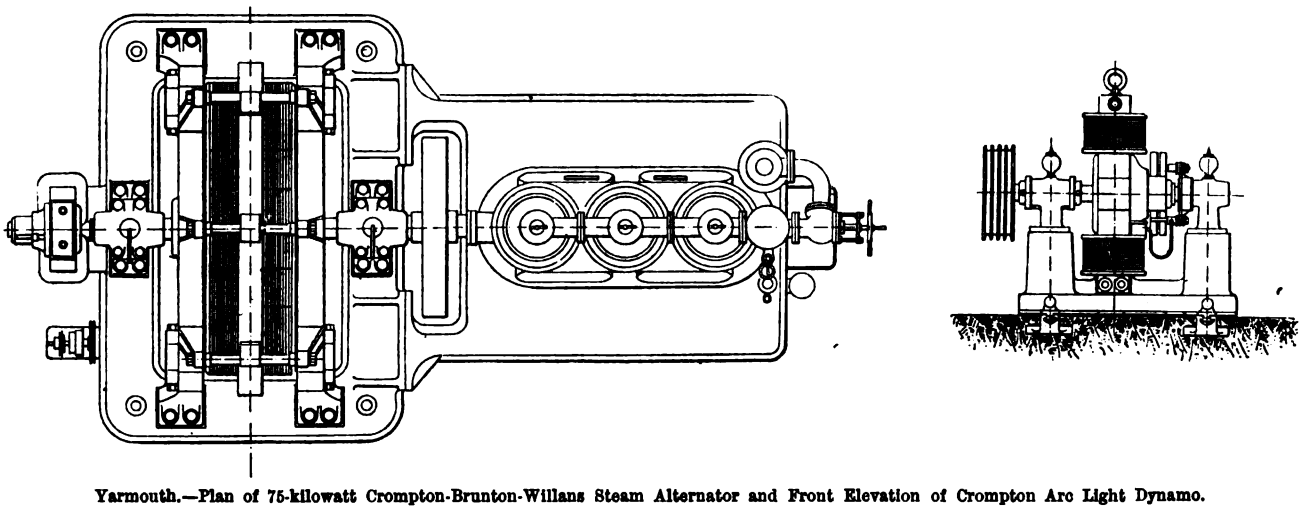
As far as the public lighting is concerned, the Corporation may be said to have been liberal in the adoption of arc lamps, there being no less than 50 10-ampere direct and 10 15-ampere alternating current lamps. The lamps, which are of the Crompton-Pochin type, are arranged on cast-iron standards, the centre of the lamp being 22ft. from the ground. The arc lamp standards were furnished by Messrs. W. MacFarlane and Co., of Saracen Foundry, Possilpark, Glasgow. In the case of the alternating-current arcs, a transformer, not placed in the base of the post, but in a concrete chamber near it, is provided for reducing the 2,000 volts to 50 volts. By means of a switch in the base of the lamp standard any one or more direct-current arc lamps can be switched out of circuit without interfering with any of the others.

The total capacity of the station for incandescent lighting is 5,000 8-c.p. lamps installed, or 3,000 simultaneously alight. Already some 1,500 lamps have been applied for, whilst including the lighting of the Municipal Buildings and the Fish Wharf, this number is increased to 2,500 lamps. Apart from this, further applications for a supply are constantly being received, so that it is probable that the output of the generating station will before long all be taken up. A supply of electrical energy is already available in Admiralty-road, Queen's-road, part of Nelson-road South, Albert-square, Marine-parade, Regent-road, King-street, Market-place, Market-row, Broad-row, Hall Quay, Regent-street, part of Alma-road, and part of Blackfriars-road and Camden-road.

The Corporation undertake to lay the supply wires to terminals immediately within the consumers' premises. No charge is made if the distance from the mains does not exceed 60ft., and provided, where it is necessary to fix a transformer, that it is not essential or desirable to build a transformer-chamber. If it is required to build a chamber of brick, it will be constructed by the Corporation, at a cost not exceeding £3, payable by the consumer. The installations are to be wired and maintained at the consumers' expense, and before electrical energy can be supplied the Corporation will test and approve of every installation. Should any defect be subsequently discovered, the Corporation may discontinue the supply until the defect is remedied to its satisfaction. Consumers are to give the officers of the Corporation access to their premises for the purpose of inspection or reading the meter at all reasonable times.

Yarmouth.—Front and End Elevations of 75-kilowatt Crompton-Brunton-Willans Steam Alternator.





Yarmouth.—Plan of 75-kilowatt Crompton-Brunton-Willans Steam Alternator and Front Elevation of Crompton Arc Light Dynamo.

The meters will be fixed on consumers' premises in a convenient position. The meter, if the property of the Corporation, will be let on hire at the following quarterly rent charge: up to 50 lamps of 8 c.p., 2s. 6d.; above 50 lamps, for every additional 50 lamps or additional part of 50, 2s. 6d. No additional lights or wires are to be used until they have been tested and approved by the Corporation. In all cases where arc lamps, motors, or other apparatus are intended to be used, special arrangements must be made.

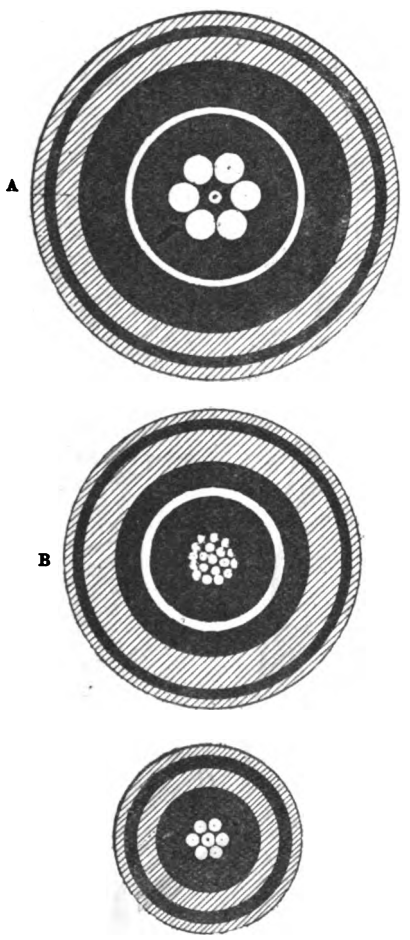
Conclusion.

Judging from the tangible form which the electric lighting undertaking has now assumed, the Corporation have now no cause to regret the consideration of the subject of introducing a municipal supply for so many years, although seeing that the supply of gas is in the hands of two companies, we should have thought the scheme would have been completed ere this. Nevertheless, now that the

Digitized by Google

station is on the eve of inauguration, congratulations should be extended to the Corporation for having brought the electric light scheme to its present position, and to Messrs. Crompton and Co. for having so ably carried out the whole of the contract.

Gas is sold in that portion of the town now electrically lighted at the rate of 3s. 2d. per thousand, and in the other part of the borough on the other side of the river at 5s. 2d. per thousand. Even in the former case, with the judicious use of switches the electric light should compete strongly with gas, whilst in the latter, gas must largely give way to the electric light. Fancy paying 5s. 2d. per thousand for gas when one can obtain a more economical, a more healthy, and a better light for less money when supplied, as the Corporation intend to do in that district, at 6d. per unit. Extensions in that part of the borough, as subsequently referred to, are proposed on a fairly large scale, and we have no doubt as to the ultimate result.



Yarmouth—A. Section of High-Pressure Double-Concentric Lead-Covered Armoured Cable with Paper Insulation. B. Section of High-Pres ure Double-Concentric $^{19}/_{18}$'s Armoured Cable. C. Section of $^{7}/_{16}$ Single High-Pressure Cable.

In wishing success to the Yarmouth station, we must tender our thanks to Mr. W. H. Preece and his son (Mr. A. H. Preece), the consulting engineer, who are responsible for the electrical portion of the undertaking; to Mr. J. W. Cockrill, the borough surveyor, who designed the buildings; to Mr. A. W. Ranken, the clerk of works for the plant, and who will probably remain as the municipal electrical engineer; to Mr. H. H. Reynolds, A.I.E.E., representing Messrs. Crompton and Co.; and to Mr. H. Arkell, the representative of the British Insulated Wire Company, Limited, of Prescot. Mr. S. Lee Vincent, it may be mentioned, was clerk of works for the buildings.

RULES FOR INSTALLATION WORK AT YARMOUTH.

The Corporation, for the guidance and information of consumers proposing to have their premises fitted for the electric light, have issued the following rules. The Corporation do not take any responsibility with respect to any installations, and they impress on intending consumers the importance of having the work carried out by competent contractors.

Service.—The Corporation will, at their own cost, lay the necessary service lines, provided the distance from the main does not exceed 60ft.; the cost of any further length of service line must be borne by the consumer. The main fuse will be supplied by the Corporation; it will be placed in position by them and sealed. Under no circumstances must the consumer or his contractor in any way interfere with the main fuse, which remains the property of the Corporation. A main double-pole switch of an approved type must be supplied and fixed by the consumer between the meter and the main fuse. The Corporation reserve the right to settle the position of the transformer (if any), meter, main fuse, and main switch.

Meter.—The Corporation will supply and fix a suitable meter at the following rental per quarter: 2s. 6d. for every 50 8-c.p. lamps or fraction thereof. The meter to remain the property of the Corporation.

General Rules.—The whole of the work in the installation must be of the highest class, and carried out in accordance with the rules of the fire insurance company in whose office the building is insured, or, if not insured, in accordance with the rules of the Institution of Electrical Engineers.

Conductors.—All conductors to be of pure copper, according to Matthiessen's standard of pure copper, and of such sectional area that the current in them shall not exceed 1,000 amperes per square inch, their area to be so proportioned to their length that the fall of pressure between the supply terminals and the farthest lamp shall not, at full load, exceed two volts. All conductors of larger sectional area than No. 14 S.W.G. should be stranded. No conductor to be used of less sectional area than No. 18 S.W.G., except in the case of flexible cords, which may be equal in section to No. 20 S.W.G. All copper wire must be tinned.

Insulation.—All conductors to be highly insulated and mechanically protected by means of tape and braid. Flexible cords to have a waterproof insulation. The insulation resistance of the conductors to be not less than 600 megohms per mile.

Casings.—All conductors to be placed in hard wood casings, except under special circumstances, and with the approval of the electrical engineer to the Corporation, the casing to be coated both inside and out with varnish or other waterproof composition when placed in damp situations. The covers of all wood casings to be screwed and not nailed down. Metal staples must under no circumstances be used for fixing conductors. In special cases, however, metal saddles may be employed, subject to approval.

Fittings.—All fittings and electroliers must be insulated at the base. Fittings must not be wired with flexible cord. The wiring of gas fittings is expressly prohibited, unless they are efficiently insulated from the gas-pipes and duly approved.

Switches.—All switches, fuses, etc., to be of fireproof construction, and to have incombustible bases. All switches to have substantial rubbing surfaces, and to have "quick-break" action. No switch to control at one time more than 20 8-c.p. or 10 16-c.p. lamps, or one high candle-power lamp.

Fuses.—All branch circuits to be protected by two single-pole fuses. A single-pole fuse to be fixed at the origin of every flexible cord. All fuses to be of an approved type and easily accessible. Magnetic cut-outs are not to be used in any case, unless previously approved by the electrical engineer.

Voltage.—The pressure will be 100 volts at the consumer's terminals, and the lamps installed must be of corresponding voltage.

Arc Lamps.—When it is intended to use arc lamps, the electrical engineer must first be consulted in the matter, and the type of lamp, choking coil, etc., must be subject to his approval.

Testing.—The Corporation will not supply current to any installation (1) if there are any temporary wires or fittings; (2) if the whole of the work is not complete and all fittings fixed; (3) if when testing with the full pressure of 100 volts, the insulation resistance should be below the follcwing standard—viz., 75 megohms divided by the number of lamps. Should the installation prove defective when tested by the engineer to the Corporation, a fee of 10s. 6d. must be paid before the second and before every subsequent test is made.

Alterations and Additions.—No alterations must be made, or any additional lamps installed, until a notice of seven days in writing has been given to the Corporation. Failure of such notice may render it necessary for the entire supply to be cut off.

Leakage.—In the event of the insulation resistance of an installation falling below 5,000 ohms, after a supply has been turned on, the whole of the installation will be cut off until the fault has been put right. Any expenses the Corporation are put to in finding such fault must be repaid by the consumer. The Corporation reserve the right to test any installation from time to time.

PROPOSED EXTENSIONS AT YARMOUTH.

The central electric light station at Yarmouth only deals with that portion of the borough situated on one side of the River Yare, but as representations were made of defective street-lighting in St. Andrew's Ward, on the other bank of the river, Mr. J. W. Cockrill, A.R.I.B.A., A.M.I.C.E., the borough surveyor, was requested some time ago to draw up a report on the subject of introducing the electric light in that district. This report, of which an abstract is given below, was brought before the Electric Lighting Committee last week, but its consideration was deferred for six months.

The ward is now lighted by 205 gas lamps, consuming five cube

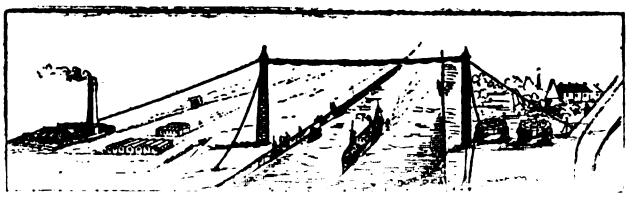
Digitized by Google

feet per hour, and one lamp of larger power consuming 15 cube feet per hour. The cost last year was £825. 12s. 8d., at the rate of £4. 1s. 3d. per lamp per annum for the 203 lamps then fixed. Each lamp is estimated to have a lighting power equal to 16 candles, a standard at which it is believed they are maintained. The cost of the paraffin lamps, including renewals, repairs, lighting, cleaning, etc., has been about £2. 15s. per annum per lamp; their lighting capacity is equal to the gas lamps, and very few complaints have reached the surveyor about them during the eight years they have been in use.

To light the whole district with arc lamps would involve fixing about 120 lamps, at a cost of £1,200 per annum in excess of the present gas bill. The estimates have therefore been based on lighting with 34 arc lamps the Southtown-road and High-street from the foot of the bridge to the Gorleston tramway terminus, Feathers' plain, and to light the remainder of the district with 25-c.p. incandescent lamps at the points now lighted with gas. This would cost about £300 per annum in excess of the sum now paid for gas after making allowances for paying the proper proportion of interest and sinking fund chargeable to this part of the installation. The sub-committee charged with inspecting the electric light installations in other towns some time since reported adversely as to street-lighting by incandescent lamps, and in several towns where they were tried for lighting the public streets they have been given up. At Chelmsford, where the sub-committee saw them in use, they are still running and giving every satisfaction, and in several small towns in Belgium and Germany, which the surveyor has recently seen, they are at work very satisfactorily. The capital expenditure involved in carrying out this scheme is as follows:

Additions to buildings	£500
Boiler, engines, and dynamos	2,500
Crossing river	600
Street mains and transformers	6,400
Arc lamps and posts, and incandescent lamp-posts and brackets	1,000
	£11,000

The above estimate provides for putting in plant and mains for installing about 3,000 private lights, a number which the surveyor thinks would be readily taken up, as the cost of electricity at 6d. per unit is less than the price of gas on that side of the water. The revenue derived from this amount of private lighting would be about £1,500 per annum, upon which, of course, some profit would be made. The question of crossing the river has had considerable attention, and Mr. Cockrill has designed several methods of carrying the cables under water, but the cost of any method will be quite £500 more than the estimate previously given. The scheme shown on his drawings, and allowed for in the estimates, is much simpler, more readily accessible, and much less liable to accidents than any method of carrying the cables under the river bed.



Yarmouth.—Suggested Arrangements for Carrying Cables Over the River.

The height at which the surveyor proposes to cross the river is 160ft. above the highest part of the quay, which, after making allowance for the "sag," should leave 155ft. at least clear headway between the cables and high-water mark. The masts would be light-looking wrought-iron lattices, only occupying ground the size of an equilateral triangle of 15ft. side, stayed back on the east side to the site of the electric light station, and on the west side to the triangular piece of ground on the south of the Southtown gasworks; all stays cross the roads at considerable height and would be no obstruction. The cables which it will be necessary to cross the river with are four arc lighting cables, two high-pressure cables for street-lighting by incandescent lamps, and two high-pressure mains for private lighting, and as these must be in duplicate, there will thus be 16 mains to be supported. A rope would be provided for running a car by which the cables could be constantly under inspection and always accessible for repairs. The sketch shows the class of structure which would be needed. The scattered nature of the district is the cause of the expense being so great, the public and private lighting together requiring nearly 35 miles of mains.

SUBMARINE CABLE GRAPNELS.

Two new forms of cable grapnels have been brought out by Messrs. Johnson and Phillips, of London and Charlton, who make a speciality of all kinds of apparatus for the laying and repair of submarine cables. These grapnels, which have been devised by Mr. Claude Johnson, are illustrated herewith. In Fig. 1 is shown a sectional elevation of his collapsible prong grapnel for the recovery of cables lying on rocky bottoms, whilst in Fig. 2 its outward appearance is represented. Any one, or all, the prongs can retire within the shield either before or after the cable is hooked, and no formation of rocks which could possibly stop the progress of the dragging, or injure the instrument, can be imagined.

The principle of the automatic movement of the prongs of this grapnel are essentially different to a grapnel having retractile prongs. In the latter form the prongs open outwardly, thus practically increasing the size of the instrument, and the expanded prongs are in their weakest position to resist strain from contact with rocks. It will be observed that in Mr. Johnson's device the reverse action takes place, and the prongs cannot be injured.

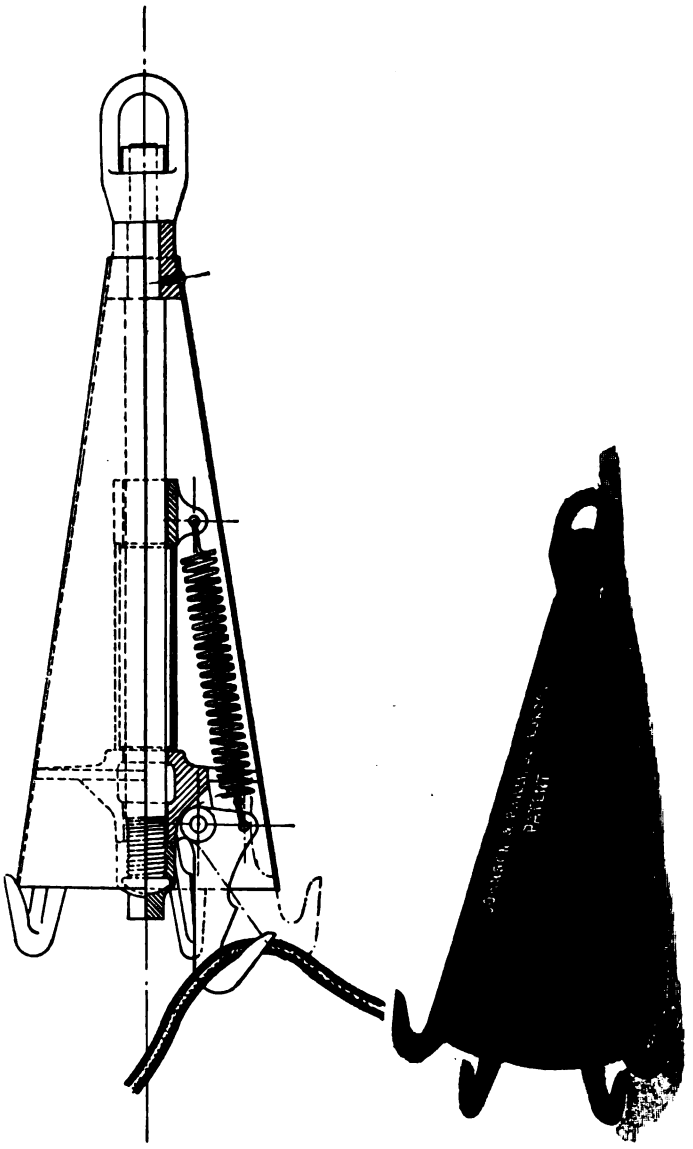


Fig. 1. Fig. 2.

The second form of grapnel is intended for the recovery of cables in mud bottoms. This grapnel has two steel prongs, which are comparatively thin but deep in section, so as to offer little resistance to their penetration into the mud. The prongs are connected to one end of a broad flat plate which constitutes the shank, the plane of which is at right angles to the plane of the prongs. On dragging with this grapnel the shank slides with its flat face on the surface of the mud, whilst the downward-directed prong penetrates to its full length into the mud so as to seize the cable embedded therein. Those engineers who are engaged in the repair of submarine cables are well aware of the utility of grapnels which will drag rocky bottoms without injury to the prongs, and also of the value of reliable grapnels for the recovery of cables from muddy bottoms, and for these reasons the two new forms of grapnels described above will be highly appreciated.

NEW DESIGN OF CONTINUOUS-CURRENT DYNAMO.

Two or three weeks ago we recorded the opening of the new electrical engineering works of Messrs. Thomas Parker, Limited, of Wolverhampton, and we are now enabled to give illustrations of the company's new design of continuous-current dynamo.

As will be seen from Fig. 1, one of the novel and special features of this dynamo is the fact that the pole-pieces are cut through and hinged, so that they can be turned back to allow of examination or taking out of the armature by a direct vertical lift, and without unsetting the bearings. The hinge is placed at the angle of the pole-piece, so that when turned back halfway the magnet ferrule can be lifted off (after the armature has been removed) without uncoupling the hinged piece. This arrangement allows of machines being fixed in confined spaces, which would not be suitable with the ordinary type of machine, where the armature has to be threaded in to or out of the magnets. There is also considerably less risk of damage in withdrawing or replacing the armature. The arrangement of the machine with the pole-pieces closed is shown in Fig. 2.

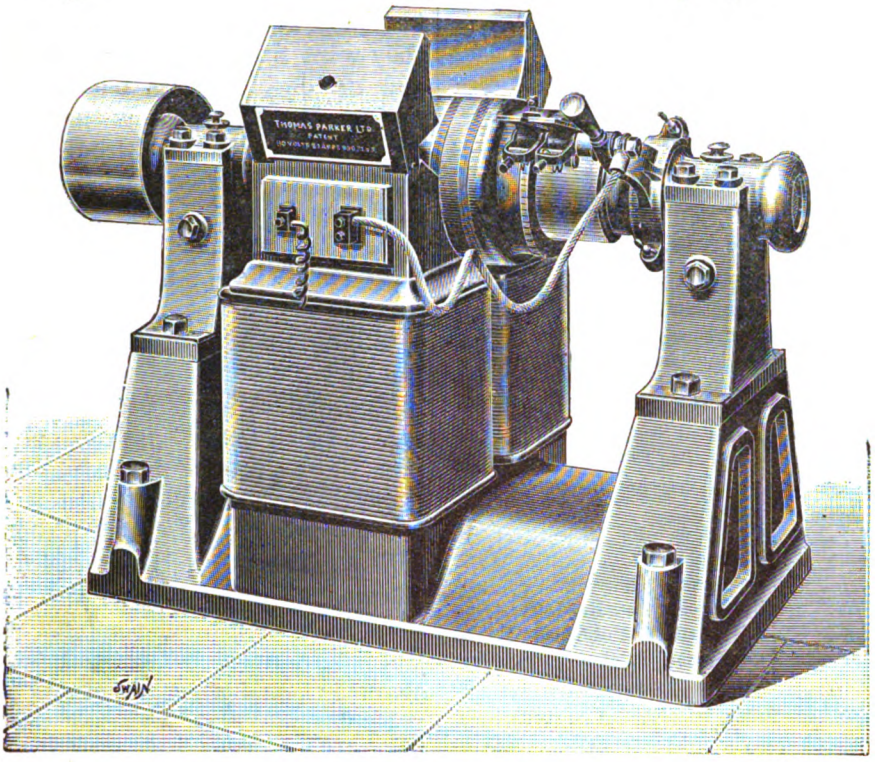

FIG. 1.—Parker's New Continuous-Current Dynamo, the Poles being shown turned back.

An oil-well is provided in the pedestal underneath the bottom of the bearing (the bottom bearing being continuous); a ring runs in this well and over the top of the shaft, giving continuous lubrication. Where machines are coupled direct to high-speed engines the armatures are arranged at the bottom, the pole-pieces in this case also being cut through, so that the upper portion of the magnets can be lifted away and the armature then lifted out. The armatures of these machines are coil wound under the Eickemeyer patents, and by means of these new arrangements the putting in or taking out of an armature is rendered not only much more simple, but it also occupies far less time than is required by the old method.

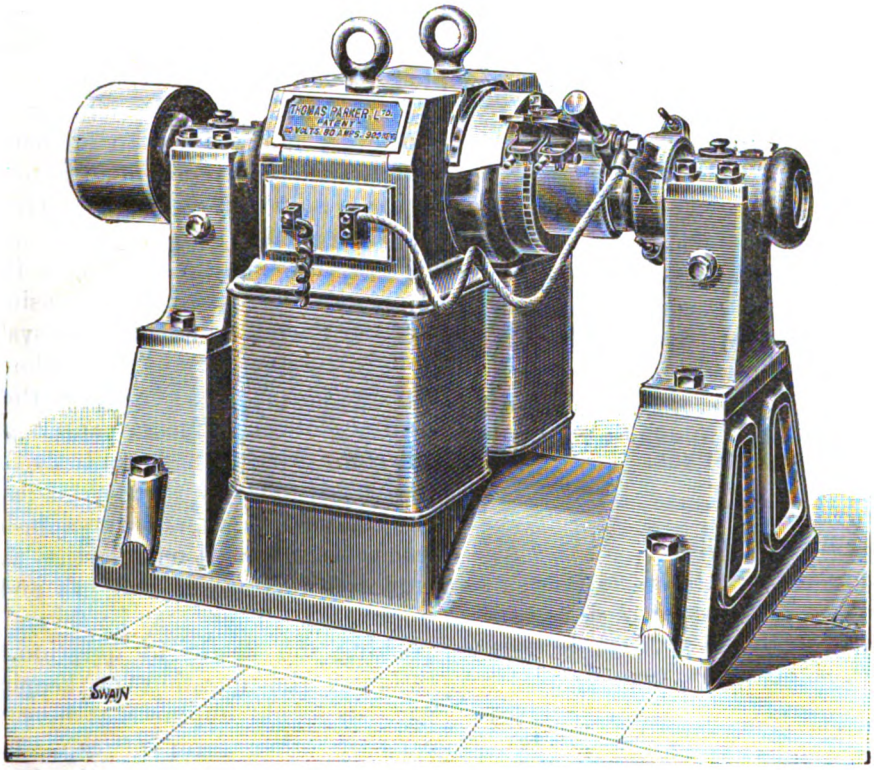

FIG 2.—View of Parker's Continuous-Current Dynamo, with the Pole-pieces closed.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—

United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

EXPLOSIONS.

A lot of rubbish has been printed recently in the daily papers anent the so-called dangers of underground electric light wires and cables, and no doubt more twaddle of a similar kind will follow from time to time. It was just the same with gas-mains when they were first laid down. But that is long ago, and no one, at least outside the electrical and engineering Press, now says anything of the hidden peril resulting from the presence of gas existing everywhere below the surface. Of the great risks due to its use in dwelling-houses and other places, ample proof is afforded week by week. It was, we believe, Sir Frederick Bramwell who recently stated that the subsoil of the Metropolis is saturated with coal gas escaping from leaky mains, and that it was scarcely possible to make a hole in the ground at any spot without encountering this gas. It does not like its rival, electricity, and manifests its displeasure by exhibiting a great affinity towards it. The affection, it is needless to say, is not of a mutual kind, and although electricity has kept as far as possible to itself, yet coal gas has followed up its embraces, with the result of explosions in underground conduits and junction-boxes. But there must be an end to incidents of this character—and what is that end to be?

Explosions have occurred recently in junction-boxes in the City where the presence of coal gas has been found, and where lead-covered concentric cables laid in iron pipes are used. They have also taken place in St. Pancras, where bare copper mains are laid down, an enquiry into the latest of these having been held yesterday, and which is referred to in another column. Kensington, two or three years ago, was the scene of a similar explosion in connection with a culvert system; but London is not alone in this matter. Glasgow, and one or two other towns, have had a similar experience. It is, however, unnecessary to further dilate upon this point, the occurrence of most of these explosions being of so recent date as to be fresh in the minds of our readers.

Now, the question arises, is it not possible to overcome this apparently increasing difficulty in connection with the underground systems of mains of supply companies and local authorities? We think so; but how? Gas permeates the subsoil, and our central-station engineers cannot get rid of it from the soil. That being admittedly the case, the alternative is either to prevent the leakage of gas into the conduits, pipes, and junction-boxes, or to ventilate these in such a manner that the formation of an explosive mixture of coal gas and air is rendered impossible. There may be several means of accomplishing the desire in question. Take first, for instance, the question of keeping out the coal gas. It would appear that by placing a clamping cap, or other form of cap, over the ends of spare pipes entering junction-boxes, and airtight caps over the ends of cable-carrying pipes entering the boxes, suitable provision being made for the admission of the cables, the difficulty would be overcome, especially with the use of ventilating pipes arranged at certain intervals. But even if the walls

Digitized by Google

of the junction-boxes are bricked and cemented and then covered with some impermeable composition, the contingency of gas entering and getting mixed with air so as to form an explosive mixture, will always be present. The method, in fact, does not seem to possess the great desideratum of absolute immunity. Another method of preventing the admission of gas—namely, the use of oil-insulated mains and distributors—may be mentioned. This system has now been in use in this country for some years, and there is, we believe, not a single case on record where an explosion has occurred in towns where this type of main has been put down.

As to permitting coal gas to play at its own sweet will, there is reason to assume that this can be allowed with proper care. It is purely a matter of ventilation. Not, however, in the sense of the doubtful expedient of erecting pipes alongside buildings to carry away coal gas, but in the direction of ensuring an efficient ventilation of the conduits and pipes. This can be accomplished by forcing through the conduits and pipes, by means of a blower, air which has previously been dried by being passed through a drying mixture. This system has, if we remember rightly, been adopted with considerable success at Newcastle and Cambridge, and one or two other towns, and is about to be introduced at Bedford. In fact, the Newcastle and District Company have forced air through their system of pipes and joint-boxes for five years, and no trouble has been experienced from either gas or moisture.

In the foregoing remarks we have endeavoured to briefly indicate methods which we think will tend to minimise, if not entirely obviate, the danger of explosions; and we shall be glad to learn the experience of central-station engineers on this subject, which is assuming considerable importance at the present time. It is not a matter to be lightly treated, but one which must be seriously considered and satisfactorily solved.

BUSINESS DURING 1894.

(Continned from page 23.)

Delaware Hard Fibre Company.

The representative of this company in this country, Mr. J. Burns, of 15, Long-lane, E.C., reports that the past year has been one of continual progress, and that the company have had to acquire extended warehouse room for the larger stock needed to execute orders promptly. Their stock of sheets, rods, and tubes is now very complete, and special attention is given to the supply of washers and special shapes.

W. T. Henley's Telegraph Works Company, Limited.

This company report that their business during 1894 showed a very satisfactory increase over that of 1893, and that, contrary to their experience of previous years, they actually had no slack time whatever during 1894. This favourable position is attributed to a great extent to the efforts of the company's branches, installation work having been very stagnant in the London district for some months out of the year. The Manchester, Bradford, and Glasgow districts have apparently been the foremost as regards amount of work done, and taking into consideration the fact of the company having secured, among others, valuable contracts for Glasgow, Edinburgh, and St. Pancras, and that their general trade has been good, the company have every reason to be satisfied with the year's work.

Liverpool Electric Supply Company.

The Liverpool Electric Supply Company, Limited, have during the past 12 months largely increased the number of lamps supplied from their mains, the total supplied now being equivalent to 31,000 16-c.p. lamps. During the year numerous installations have been carried out both in connection with the company's system and by means of isolated sets of plant. Among the latter may be mentioned the lighting of Childwall Hall for Mr. H. G. Schintz, and a large installation at the Albert Dock for the Mersey Docks and Harbour Board.

Manchester Edison-Swan Company.

During the past year the Manchester Edison-Swan Company have been exceptionally busy. The principal installation they have carried out has been the central station of the Altrincham Electric Supply, Limited (for which they obtained the complete contract), which is an alternate-current station, working at 2,000 volts, and supplying current over a large district of Altrincham and Bowdon. The alternators used are of the Manchester Edison-Swan Company's make. The company have also constructed central-station apparatus for several corporations and supply companies, including the large switchboard for the Bolton Corporation. Amongst the private installations which have been carried out are those for Mr. S. Armitage, of Pendleton; Mr. F. W. Travers, of Bowdon; Mr. L. Pilkington, of Pendleton; and Mr. E. Pilkington, of Clifton; also installations on the premises of Messrs. J. L. Barker, W. O'Hanlon, W. Dykes, A. Coupe, J. Barningham, all of Bowdon; at Mr. G. W. Bonson's, Altrincham; and Mr. Thos. Townley-Townley Parker's, Preston. Amongst the shops, hotels, warehouses, etc., which have been lighted by this company may be mentioned the following: Brooke, Bond, and Co., Manchester; Technical School, Leigh; Empire Palace, Birmingham; Textile Mill Company, Oldham; Bull's Head Hotel, Birmingham; Garrick Hotel, Manchester; Marshes Restaurant, Manchester; Mr. I. Frankenburg, Salford; Manchester Coffee Tavern, Manchester; New Circus, Bolton; Mr. A. Cowsill, Altrincham; J. Moss and Sons, Manchester; W. T. Glover and Co., Salford; W. Graham and Co., Redfern and Son, Beaumont Bros., Brookfield, Aitchison, and Co., J. Wilkinson and Co., J. Woolley and Sons, and Corn Exchange, the last seven of Manchester; Axe and Cleaver Hotel, Altrincham; Swan Hotel, Bolton; Congregational Church, Bowdon; W. Thorburn, Sons, and Co., Manchester; Union Bank, Leigh; Maxwell and Tuke, Manchester, and many others.

Willans and Robinson, Limited.

We have received some information from Messrs. Willans and Robinson of their work during the year, and which shows how large a proportion of the central stations in progress are being equipped with the Willans central-valve engine, which is steadily coming into still more extended use. The following figures are very remarkable in these days of bad trade.

Digitized by Google

Engines ordered in	1891	11,100 h.p.
,, ,,	1892	14,300 ,,
,, ,,	1893	18,950 ,,
,, ,,	1894	26,624 ,,

With the total power the size of the engines is also increasing, the orders booked including eight engines of 700 h.p. each, 13 of 360, four of 300, 12 of 200, six of 240, and two of 1,400 each (these last, though for driving dynamos, are not for electric lighting), while the average size of the whole number is 166 h.p., a result which could scarcely have been foreseen by the makers of high-speed engines a few years ago. The principal central-station orders received during 1894 were from or on account of the following: Westminster Electric Light Company, London (additions), 1,280 h.p.; City of London Lighting Company (additions), 5,600 h.p.; Kensington and Knightsbridge Company, London (additions), 360 h.p.; Liverpool Electric Light Company (additions), 600 h.p.; Norwich Electric Light Company (additions), 270 h.p.; Birmingham Electric Light Company (additions), 300 h.p.; Chelsea Electric Light Company, London (additions), 655 h.p.; Blackburn Corporation, 560 h.p.; Edinburgh Corporation, 1,750 h.p.; Sunderland Corporation, 354 h.p.; Yarmouth Corporation, 420 h.p.; Cheltenham Corporation, 360 h.p.; Brighton Corporation (additions), 600 h.p.; Glasgow Corporation (additions), 720 h.p.; Tunbridge Wells Corporation, 300 h.p.; Aberdeen Corporation (additions), 400 h.p.; Whitehaven Town and Harbour Trust (additions), 120 h.p. The largest of these orders—that for the City of London Lighting Company (through the British Thomson-Houston, Limited)—includes eight engines of 700 h.p. each, which will be coupled direct to Thomson-Houston alternators running at 300 revolutions a minute. The following private installations may be mentioned: United Alkali Company; Messrs. Albright and Wilson, Oldbury (additions); Army and Navy Stores, London. The following foreign contracts may also be noted: Liège lighting, Belgium; St. Petersburg lighting; Caen lighting, France (additions); Liège electric tramways; Dutch State Railways (additions). The above-mentioned figures amount to over 18,600 h.p., and of this about 12,450 has been ordered by those who are already users of the Willans engine. During the past year engines ordered previously have been erected and started in the following places: Birmingham Grand Hotel; Messrs. Berkenbusch and Co., Brunswick (flour mill); Messrs. Gunning and Campbell, Belfast (flax mill); Nottingham Corporation electric light station; Messrs. Albright and Wilson, Oldbury; Rotterdam electric light station; Bradford Corporation electric light station (additions); Holborn Restaurant, London; Hampstead Vestry; Biarritz lighting; St. Pancras Vestry (additions); Glasgow post office; Hove lighting (additions); Messrs. McKechnie, Widnes; London, Brighton, and South Coast Railway, Newhaven (additions); Dewsbury Corporation electric light station; Bristol Corporation electric light station (additions). The Willans engine up till recently has been made in comparatively small sizes, not exceeding 350 h.p., and its chief use has been for electric lighting, for which its high speed specially fits it; but it is now being made in larger sizes, and for many other purposes. The large order for the City Lighting Company of eight engines of 700 h.p. marks a new departure in electric light engineering in England, as it is perhaps the largest yet given for electric light engines, and certainly no attempt has been yet made to introduce high-speed engines of so large a size. So far as we know, the largest hitherto used have been Willans engines of about 350 h.p. running at 350 revolutions per minute. The electro-chemical industry is one which is fast growing into great importance, and in which the generating plant is run under conditions even more trying than those of electric lighting. Not only are high-speed engines a necessity, but they are kept constantly running under their full load for long periods at a time. Several engines ordered during the past year from Messrs. Willans and Robinson are for this purpose, as, for instance, those for Messrs. Albright and Wilson, Oldbury, which have to make runs of six weeks' duration without a stop; for Messrs. McKechnie, Widnes; and the United Alkali Company. Messrs. Albright and Wilson's order was given in consequence of the successful working of engines previously supplied, which have been running perfectly satisfactorily under the above conditions. In millwork, also, the Willans engine has proved successful, where its high speed and even turning movement enable it to give exceedingly steady driving. The two large engines at Messrs. Gunning and Campbell's flour mill at Belfast, and Messrs. Berkenbusch's flour mill at Brunswick, which were started in the course of last year, have now been running successfully for some six months. We understand that the first named—a triple-expansion engine—has recently been tested, with the result that the consumption proved to be under 12·8lb. of steam per indicated horse-power per hour, and while the steadiness of driving far surpasses any of the older slow-running engines, the periodic variation of speed per revolution not exceeding 0·2 per cent. of the speed (300 revolutions per minute), as shown by a Moscrop speed recorder. The Willans engine has been applied to electric traction, though not as yet in England. An order has been received for the engines for the electric tramways at Liège, Belgium, which will be started in the course of the present year, and the experience gained with the Willans engines on the electric tramway at Hobart, Tasmania, leaves no doubt as to their successful working. We understand, too, that other orders for traction work are pending. Some reference may also be made to two powerful engines which the company are making for the Heilmann electric locomotives now under construction in France. These engines are of 1,400 h.p. each, and run at 400 revolutions per minute; they are of very special design necessitated by the great power and high speed required, and by the small space and weight which can be allowed. The company exhibited two engines of 200 h.p. each, as well as a smaller one, at the Lyons Exhibition. The two larger engines were employed in lighting the buildings during the whole period of the exhibition, a work which they performed without hitch of any kind. For these two engines the company were awarded the *grand prix*. Another purpose for which the Willans engine is being employed is that of air-compressing. In this case the compressor is practically a Willans engine reversed, with certain small modifications which enable it to act as a pump instead of as a motor. It is coupled directly to and is driven by an ordinary central-valve engine. Several orders have been received for these air-compressors during the year, as well as for engines for lighting mines, driving mining stamps, etc. For some time the works at Thames Ditton have been considerably overtaxed, and Messrs. Willans and Robinson have had in view the erection of new works in which to deal with their larger engines. They have now purchased a site of about 25 acres at

Digitized by Google

Rugby, in close proximity to the London and North-Western Railway, and it is their intention to start building at once.

REVIEWS.

Electrical Engineering as a Profession. By A. D. SOUTHAM. London: Southam and Co. Official edition.

We some time ago had occasion to notice in its first form Mr. Southam's guide to electrical engineering as an occupation in life, and were able to mark with approval the issue of a work dealing with the entire subject in a fashion satisfactory on the whole. The present issue appears to be an enlarged issue of the author's original handbook, though we do not quite see the object of entitling it "official," except that the particulars of technical colleges and training institutions herein given have been "officially" supplied to the author. The first part of the new edition is essentially Mr. Southam's personal contribution to or criticism of the discussion respecting a parent or guardian's proper duty towards the youthful would-be engineer: and he deals with the matter very largely upon the lines we advocated ourselves a year or two ago, when a small epistolary parliament was held in these pages in order to thoroughly ventilate the opinions of those best fitted to speak upon the subject. Mr. Southam both gives and quotes very sound advice, which may be read with advantage by all interested, not merely by parents, but by youths and students also. The remainder of the book (which has now grown to a volume of some 200 pages) comprises descriptions of the leading technical colleges and institutions, with all the necessary information as to fees, etc., and also of those electrical and engineering firms or companies who receive apprentices. We note amongst these one or two whose names can hardly be called household words, though probably Mr. Southam has sufficient reason for including them. Speaking generally, the book may be commended as the best of its kind, a number of capital illustrations helping very materially to increase its use and appearance.

Standard Methods in Physics and Electricity Criticised; and **A Test for Electric Meters Proposed.** By H. A. NABER. London: 1, 2, and 3, Salisbury-court, E.C.

This is rather a curiously-written book, the author of which has devised a somewhat novel form of gas voltameter. He states it as being his opinion that a good appliance of this kind is well adapted not only for standardising large-current galvanometers, but other instruments also, besides being capable of use in ordinary measurements, and even as an electricity meter. This position he discusses at some length in a series of chapters possessing considerable interest, not their least value being the utterly unconventional tone in which they are written.

INSTITUTION OF ELECTRICAL ENGINEERS, Jan. 10.

At last night's meeting of the Institution, the following candidates were balloted for:

Foreign Members.—Prof. André Blondel, electrician and engineer of the Ecole des Ponts et Chausseès, and of 2, Boulevard Raspail, Paris; and H. Ward Leonard, 44, Broad-street, New York.

Associates.—William John Aubert, Shepperton, Middlesex; Ernest E. Bartlett, 5, St. Frideswide-terrace, Osney, Oxford; William Church, Marlborough House, Pall-mall, S.W.; E. S. Curtis, Box 96, Johannesburg; Charles Manners Donnie, 36, Queen-street, London, E.C.; Reginald Falshaw, 17, Princes-street, Harrogate; John Raven Frankish, Town Hall, Melbourne; Julius Frith, The Owens College, Manchester; Alfred Sharman Giles, 48, James-street, Buckingham Gate, S.W.; Arthur Hattersley, Trinity Wharf, Blackwall, E.; William Jones, 2, Middleton-street, Hull; Lionel James Langridge, Royal Insurance Company, Lombard-street, London, E.C.; A. B. Layton, 4, Bellevue terrace, Charlton-road, Blackheath, S.E.; Samuel Arthur Mahood, "West Lynne," Comer-road, St. John's, Worcester; George W. Money, 36, Windermere-street, Gateshead-on-Tyne; Joseph Allison Newton, Melbourne, Australia; Alfred William Sharpe Pocklington, 6, Cressingham-road, Lewisham, S.E.; Carl W. Schaefer, the Eastern Telegraph Company; Alfred Schwartz, A.K.C., A.M.I.C.E., Ivy House, Woodford Green, Essex; Henry John Wagg, 40, Bryanston-square, W.; Arthur Thomas Walmsley, 9, Victoria-street, Westminster, S.W.

Students.—Dennis H. Bayley, Cliff Lodge, Southfields, S.W.; Frederick Simmons Grogan, 33, Criffel-avenue, Streatham Hill, S.W.; Luis Ebenor Hazera, Faraday House, Charing Cross-road, W.C.; C. McCarthy-Jones, Elm View, Woodside Park, N.; H. J. Saunders, 117, Sutherland-avenue, Maida Vale, W.; John Ortelli Zerega, Faraday House, Charing Cross-road, W.C.

The minutes of the previous meeting having been read, the retiring president, Mr. A. Siemens, presented the Salomons scholarship to Mr. E. E. Holmby.

Prof. Ayrton proposed and **Sir David Salomons** seconded a vote of thanks to the retiring president, this being unanimously carried.

Mr. R. E. Crompton, the new president, then delivered his address, stating that he would do so mainly from the mechanical point of view of an electrical engineer.

PRACTICAL NOTES ON DYNAMO CALCULATION.*

BY ALFRED E. WIENER.

(Continued from page 11).

40. *Actual Leakage Factor of Machine.*—By a very simple method devised by the author the total flux, ϕ'', of magnetic circuit of a dynamo can be calculated from the running data of the completed machine, and the actual leakage factor for any particular dynamo can therefore be found for the formula,

$$\lambda = \frac{z \times \phi''}{\phi} = \frac{\phi'}{\phi} \quad . \quad . \quad . \quad . \quad (135)$$

where ϕ'' = total flux of magnetic circuit, in webers, calculated from test data;

ϕ' = total flux in entire magnet frame, in webers;

ϕ = useful flux cutting armature conductors, in webers, from formula (91) or (92) respectively;

z = number of magnetic circuits in machine.

The writer, by employing his method above referred to, has figured the actual leakage factors for nearly 200 practical dynamos, of which the complete test data were at his command; and by combining his results with the researches of Hopkinson, Lahmeyer, Corsepius, Esson, Wedding, Ives, Edser, and Puffer, has averaged the following Table LII. of leakage factors for dynamos of various types and sizes, which is to be used for obtaining an approximate value of the leakage coefficient for the preliminary calculation referred to in Chapter 36.

From this table the general rule will be noted that the factor of leakage is the greater the smaller the dynamo, which is due to the difficulty, or rather impossibility, of properly diminishing the magnetic circuit in small machines. In these, on account of the comparatively large space occupied by the armature winding, the length of the air-gaps is much larger, and the relative distances of the leakage surface much smaller in proportion than in large dynamos. The permeance of the air-gaps, therefore, is relatively much smaller, while the permeances of the leakage paths are considerably larger, comparatively, than in large machines, and formula (110) in consequence will produce a high value for the leakage coefficient for a small dynamo.

It further follows from Table LII. that the leakage factor for various types and sizes of dynamos varies within the wide range of from 1·10 to 2·00, which result agrees with observations of Mavor, who, however, seems not to have considered capacities over 100 kilowatts. By comparing the values of λ for any one capacity the relative merits of the various types considered may be deduced.

Thus it is learned that, as far as magnetic leakage is concerned, the horizontal double-magnet type (column 6) and the bipolar iron-clad type (column 7) are superior to any of the other types, which undoubtedly is due to the common feature of these types of having the cores of opposite magnetic potential in line with each other on opposite sides of the armature, thus reducing the magnetic leakage between them to a minimum.

Next in line, considering bipolar dynamos, are the inverted horseshoe type (column 2), the single-magnet type (column 4), the upright horseshoe type (column 1), and the vertical double-horseshoe type (column 8).

* From the *Electrical World* (New York).

Of multipolar machines the two best forms, magnetically, are respectively the inner polar type (column 13) and the radial multipolar type (column 12). In the first named of these types the magnetic types form a star, having a common yoke in the centre, and the polar pieces at the periphery; thus the distances of the leakage paths increase in direct proportion to the difference of magnetic potential, a feature which is most desirable and which accounts for the low values of λ for the type in question.

The most leaky of all types seem to be the horizontal single-horseshoe type (column 3) and the axial multipolar type (column 15). In the former type the excessive leakage is due to the fact that the magnetic circuit is suspended over an iron surface extending over its entire length, while in the latter type it is due to the comparatively close relative proximity of a great number of magnet cores (two for each pole) parallel to each other.

(To be continued.)

ELECTRICAL ENERGY—WHAT IT IS!

BY R. C. SHETTLE, M.D.

In the *Electrical Engineer* of December 7, under the title of "What is Gravity?" I put forward a theory relative to the formation of matter by which I defined the nature and cause of gravity. I pointed out that matter was endowed with various physical properties, in proportion to the quantity of the primary stuff which was differentiated for each form of matter, and to the particular character of motion which the quantities assumed under the general stress originated by the stuff undergoing formation into matter. I also described the ether as the residual stuff which had become very highly attenuated under the stress arising from the formed matter. It will be well now to consider the cause and nature of "electrical phenomena," and the relation they hold to matter under the same theory of gravity.

After what I have already stated with reference to the connection which exists between the material atoms and the attenuated original stuff, or ether, I think that the explanation of this form of energy is really very simple. The primary points for consideration are as follows: (1) That the earth is a highly porous form of matter. (2) That the interspaces are always occupied by ether. (3) That this ether exists in two conditions—(*a*) condensed on the surface of the atoms and partaking of their motions, just as the atmosphere partakes of the motions of the earth; and (*b*) in a free state and absolutely at rest, or nearly so, but, owing to its inertia and the motions of the earth, having a relative motion opposite to the motion of the matter. (4) That the ether in this state of rest or relative motion is retained in its normal degree of tenuity and tension by the stress of the surrounding masses.

Now, I venture to think that the ether is the basis of all electrical energy, and that just as under ordinary manifestations of energy the matter is the medium by which either potential or kinetic energy is perceived, so the ether is the medium by which changes of stress are shown, by whatever means they are originated. Indeed, if my theory is correct, it would seem that every change in the direction of what may be called the normal stress must be productive of effects upon the material atoms with which the ether is associated, not by friction, but by change in the direction of the strain, and these changes should be in proportion to the primary change of stress.

In formulating this theory of the cause of electrical phenomena, we have to consider (1) the free ether as the basis of the force, and that it is in direct contact with the atoms through the medium of the bound ether; (2) that its normal degree of tenuity is maintained by the stress of the formed matter; (3) that this free ether, in consequence of its inertia, has a relative motion opposite in direction to that of the earth, and as uniform in character as that of the matter; (4) that any local disturbance of these relations must proportionately affect the normal motion of the matter and the stress of the elastic ethereal medium. Therefore, in proportion as any molecular motion has been effected by friction or otherwise, and has modified the direction of stress, the stress natural to the matter must manifest itself in a direction which accords with the molecular disturbance, and the new set of phenomena must continue until the stress has resumed its natural direction by being absorbed into its normal condition. This explanation appears to me to satisfy all the points which demand attention in the evolution of static electricity, either in its terrestrial or artificial manifestation.

I will now consider dynamic or current electricity. It has been shown by Dr. Oliver Lodge ("Theory of Magnetism," page 173) that "The atoms of a particular substance—iron, for instance, or zinc—have an electric whirl of certain strength circulating in them as one of their specific physical properties. This much is certain, that the Ampèrian currents are not producible by magnetic experiments. When a piece of steel or iron is magnetised, the act of magnetisation is not an excitation of Ampèrian currents in each molecule—is not in any sense a magnetisation of each molecule. The molecules were all fully magnetised to begin with; the act of magnetisation consists merely in facing them round so as to look mainly one way in polarising them, in fact. This was proved by Beetz long ago. I will not stop to explain it further, but will refer students to Maxwell (vol. 2, chap. 6)."

I have quoted the above as having a peculiar interest in connection with my theory of gravitation and the cause of the physical properties of matter, as well as with the point now under consideration—viz., the circulation around the material atoms, not of "whirls" only, but of the very definite double helical currents which I have described. Therefore we have to recognise (1) that the earth is a reservoir of ethereal stuff which, to a large extent, assumes the form of currents circulating in helical directions around the atoms by its relative motion; and (2) that so long as the normal conditions of

Digitized by Google

stress exist, there is probably no indication of these currents, more especially as currents of electrical energy; but as soon as bodies under different degrees of stress are associated by a medium (a conducting wire, for instance) by which those various degrees of stress can be made apparent, a current of this ethereal stuff is originated (which is, in fact, only motion in a new direction) in an effort to establish equilibrium of stress. Indeed, the current would seem to be the effect of an effort of the two bodies to establish balance of stress through the connecting medium. Upon this principle, the origination of static and dynamic electric stress appears to be as simple as is the flow of water from a higher to a lower level.

I would further suggest that in the generation of electric currents, the decomposition of the zinc element is due to the disruptive influence of the two currents exercised upon the surface of the weaker of the two forms of matter, upon the same principle as the disruption of matter would be effected (as I have shown in my paper on gravity) if the normal rotations of the atoms were terminated by the collision of the two masses.

I would add that the investigations which I have conducted into the character of other natural phenomena assure me that all—not excepting even the phenomena of animal life—are capable of being explained under the theory which I have now advanced as the nature and cause of gravity.

ELECTRICITY AND PLANT GROWING.

A paper on this subject has been contributed by Mr. L. H. Bailey, professor of horticulture at the Cornell University, Ithaca, New York, to the *Transactions* of the Massachusetts Horticultural Society. The paper was divided into two parts, one dealing with the application of electrical illumination to plant growing, and the other to the use of electricity or electric currents to plant growing.

With regard to the first, the author detailed a number of experiments, and concluded as follows: The electric arc light exerts a powerful influence upon plants in greenhouses, and all species, and sometimes even garden varieties, are affected differently. This varying influence is the effort of the plant to adapt itself to the new conditions in which it is placed, and the modification undoubtedly bears some relation to the elasticity or fixedness of the organisation of the plant, and therefore to the conditions under which the species has been evolved. And it must, therefore, follow that if plants were to be subjected to the electric light through several or many generations, more or less adaptive varieties would arise, in the same manner in which plants have adapted themselves by profound variation to the requirements of greenhouse cultivation. The electric light affects plants by hastening growth of maturity, but this effect may be so powerful as to destroy the plant. The injury is avoided, however, by screening the light through a glass, or by removing the plant to such a distance that the mischievous effect of the ultra-violet rays is dissipated. I consider it to be established that lettuce can be profitably aided by the electric light, and it is very probable that many flowers can be similarly benefited. Beyond this, I can only say that the fundamental principles involved are now pretty clearly understood, and that the near future should give us results of direct economic value.

Dealing with the second part, the author mentioned the attempts made to determine the effects of electric currents or electrification upon growing plants. He then continued:

Although it is not my purpose to analyse the results of the various experiments in the application of electricity to the soil, I wish to submit a few suggestions in passing. In the first place, it has not been proved, so far as I know, that the effects are due to the mere electrification of the soil. It is quite as probable that the injuries or benefits follow some chemical or mechanical effect which the current may exert upon the soil or the interstitial air. But what I particularly wish to say is that I have not yet read of an investigation in this direction which satisfies the demands of exact experimentation. The electric plots in these experiments are provided with wires or metal plates beneath the soil, while the control plots are left in a normal condition. The placing of the apparatus in the soil requires the removal and replacement of all or a part of the earth, and the soil is therefore in a different and usually better mechanical condition than that of the control plots. Or even if the soil were to be removed and replaced in the controls, the presence of the wires and plates would of itself introduce a great element of error, for the wires would become important factors in aerating and draining the soil and probably in modifying its temperature; and metal plates would certainly be likely to influence soil temperature. It is well known that in certain cases the germination of seeds can be hastened by running a twig down to them: it becomes a means of providing oxygen from the air, and probably also of relieving the soil of some of its superfluous water. One of the important advantages of ploughing under coarse manures or green crops is the mechanical effect which follows, for every strand of vegetable fibre forms a tube for the passage of water and air. And it has long been the practice in cool countries to put earthenware or other plates beneath fruit trees to warm their feet. While I am convinced that the application of electricity to the soil may produce marked effects upon vegetation, I shall not be ready to accept the results of experiments until the control plots are wired like the others—with non-conducting material, of course—and the temperatures and humidity of the soil are given careful attention.

It is very probable that atmospheric electricity exerts a powerful influence upon vegetation. The experiments of Grandeau were designed to determine this point. Plants were grown in the free atmosphere, which is always in a greater or less state of electrification, and also in a wire cage from which the atmospheric electricity was excluded. Maize in the free air was in every way better than the other, not only in the bulk of all its parts, but in the amount of ash, and of both nitrogenous and non-nitrogenous matters. Leclèrc, who made investigations at the same time, arrived at identical results. Grandeau's conclusions are as follows: (1) Atmospheric electricity exerts a considerable influence upon the production of vegetable matter. Other things being equal, plants will develop better when exposed to the influence of atmospheric electricity. (2) Plants deprived of the influence of atmospheric electricity have, in the same length of time, given 50 to 70 per cent. less bulk and 50 to 60 per cent. less fruit and seeds than the plants subjected to normal conditions—*i.e.*, those to which atmospheric electricity has free access. (3) The proportion of albuminous matter does not appear to be sensibly influenced by the electricity, but those plants from which the electricity is withheld appear to contain less water and more mineral content. (4) Tall plants have a mischievous influence upon the development of those which grow at their feet, not only because they deprive them of heat and light, but also because they absorb the atmospheric electricity.

Celi, shortly afterwards, reached similar results, while Naudin arrived at directly opposite conclusions. But the signal results obtained by the first three experimenters are generally accepted as strong evidence that normal atmospheric electricity is in some way beneficial to vegetation, and that in the experiments of Naudin there must have been some unknown conditions which obscured the results. By far the best investigations upon the electrification of the atmosphere in reference to plant growing with which I am acquainted are those made in Finland and France by Prof. Lemström, physicist in the university of Helsingfors.

It remained to determine whether the results obtained in Finland, which were favourable, can be expected in other parts of the world, or if they are possible only in high latitudes. The scene of experimentation was now transferred to France, where cereals, garden vegetables, and a variety of fruits were treated. An incident in this experiment was the behaviour of strawberries, which were subjected to an aerial discharge of from 2,000 to 3,000 volts continuously, night and day, from the middle of April to the middle of June. The first flowers appeared upon April 29 in the treated area, and upon May 7 in the other portion. The treated plants were in every way superior

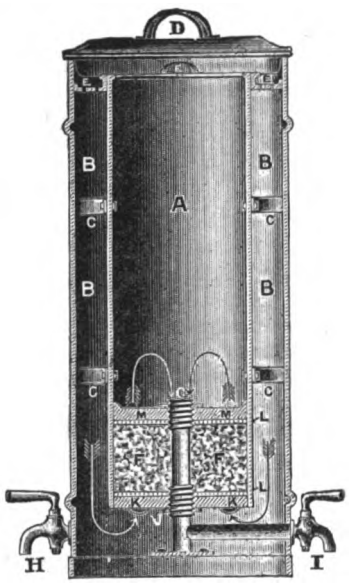
Digitized by Google

to the others until May 18, at which time there followed eight days of excessively hot weather. The treated plants languished, and the yield was much less than that of the normal area. The conclusion drawn from this interesting test is that the simultaneous action of electricity and high temperature is injurious to plants, and suggests that the electric current be discontinued in the hottest part of the day, as had been done in the Finnish experiments.

Although the remarkable experiments of Lemström have shown that the application of electricity to the atmosphere generally influences plants profoundly, and usually beneficially, it is yet undetermined just how this effect is brought about. It is highly probable, however, as Lemström himself suggests, that the modifications are not the direct result of electrification of the plants or the atmosphere, but rather follow some chemical change in the atmosphere which is engendered by the current. The experimenter is to continue his studies, and I expect to supplement them in America, for I consider it the most promising field in the many obscure inter-relations of electric energy and horticultural practice. I expect little practical result to follow any method of direct electrification of vegetation, but there is promise in those broader applications which intensify the normal processes of nature.

WILLCOX'S OIL-FILTER.

In the accompanying illustration is shown a new oil-filter, which has recently been placed on the market. This filter has



already been tested with satisfactory results in several central stations, where its adoption has resulted in great economy in oil, especially in connection with the collection of the used oil coming from the dynamo bearings. Where gas-engines are employed, this type of filter will also prove of value. It will be seen from the illustration that the construction of the filter differs somewhat from others. All the dirty oil is put into the outer chamber, and the oil is filtered by gravitation. The makers, Messrs. W. H. Willcox and Co., of 34 and 36, Southwark-street, S.E., state that the filter is one of the cheapest and best in the market. It can easily be cleaned out, it not being necessary to empty the filter to take away the dirty deposits. Referring to the cross-section, A represents the clean-oil chamber; B, the dirty-oil chamber; C are lugs on the clean-oil cylinder, so as to keep it central; D is a loose cover of the dirty-oil chamber; E is a loose cover of the clean-oil chamber, with perforated rim; F shows the filtering material; G is the clean-oil outlet tube; H represents the dirty-oil tap; I is the filtered-oil tap; J is the back-nut joint; K the lower grid; L the perforated zinc, and M the upper grid. In order to filter dirty oil the lid D is removed, and the dirty oil poured upon the lid E, when it will run through the perforation in the lid E into the dirty-oil chamber, B, forcing its way up through the lower grid, K, and the perforated zinc, L, through the filtering material, F, then when thoroughly cleansed it passes through the upper perforated zinc, L, and grid M into the clean-oil chamber, A, from whence it can be drawn off from the tap, I, through the tube, G, as indicated by the arrows. The filtering material can be easily removed when necessary.

MOUNTAIN RAILWAYS.

At the ordinary meeting of the Institution of Civil Engineers on Tuesday, Sir Douglas Fox, vice-president, in the chair, three communications having reference to mountain railways were read.

The first paper, by Mr. Sigvard Johnson Berg, A.M.I.C.E., was entitled "The St. Gothard Mountain Railway and the Stanzerhorn Cable Railway." In the great variety of systems presented by its railways, Switzerland might be said to exceed almost all other countries, especially in regard to mountain lines. The special nature of the work required for mountain railways in general, for their protection from floods, landslips, and avalanches, was first dealt with, and it was stated that only in recent years had the avalanche question been systematically studied. Avalanches were divided into two classes, described as "ground avalanches" and "snow-dust avalanches." The former occurred when a consolidated mass of snow was set in motion by thaw or other causes and descended at a comparatively slow rate, carrying earth, stones, trees, etc., along with it; the latter arose when the snow was newly fallen, and the temperature below freezing point, and they descended at a high velocity accompanied by a cloud of frozen snow-dust. A third type, sharing the character of both classes, was also mentioned. All risk from avalanches might be disregarded on a well-wooded hillside. Protection might be obtained, where necessary, in two ways: either by building the line in a tunnel or gallery, or else by works of defence adapted to arrest the movement of the snow. In constructing galleries, care should be taken to avoid placing the entrances to them in deep cuttings, and cuttings at the entrances to galleries should be levelled down on the side towards the valley. Barriers made to arrest avalanches were sometimes of dry-stone walling, and sometimes of timber or iron posts with rails or wattlework. These barriers were distributed in short lengths over the ground where avalanches were likely to originate, with their sides at right angles to the probable direction of motion. When timber posts were used, they were, as a rule, from 5ft. to 6ft. 6in. in length, and about 6in. in diameter. In steep gorges, snow bridges, like hurdles, placed horizontally in the angle of the gorge, were used to break the force of a descending avalanche, although not adequate to stop it altogether. In concluding this part of the communication, a detailed account was given of the St. Gothard Railway.

The author next described the Stanzerhorn cable railway, which ascended from the Lake of Lucerne to near the summit of the Stanzerhorn, 6,230ft. above sea-level. The line was divided into three sections, with a power station at each division. By this means a better alignment was obtained than would have been possible if one cable had been used throughout. The capacity of the line for traffic was also increased and the length of the cables reduced. The motive power was electricity, generated by a hydraulic motor at a distance of 2½ miles. The generating station also supplied power to other consumers. The power stations were furnished with steam-engines as a reserve. The line had two rails, except at loops, midway of each section where the "up" and "down" carriages passed. The gradients on the lowest section commenced with 1 in 12·5 and ended with 1 in 3·7. The other sections both began with 1 in 2·5 and ended with 1 in 1·6. The speed on the first section was 6½ft. per second, and on the others about 4½ft. per second. The whole journey occupied about 45 minutes, each section taking about 13 minutes. Each section had a fairly straight alignment, the highest section having the greatest curvature, amounting in all to 56deg. The points at the passing places were automatic, the outer rail being continuous in each case and the wheels on one side of each carriage having double flanges, while the other wheel was without flanges. No rack was used, this being considered a source of danger on such steep gradients from the possibility of the pinion mounting the rack teeth. The longitudinal section of the line approached closely to the ideal profile requiring uniform motive power. The gauge was one metre. Steel sleepers weighing 51lb. were used on the lowest section with rails

Digitized by Google

of 40lb. per yard, in 10 metre lengths, spaced one metre apart. The permanent way was anchored by vertical joists in blocks of concrete at every fourth rail joint. On the two upper sections the permanent way was the same except that iron angle-bars, 5in. by 3½in. by 5ft. long, were used as sleepers. The cable on the lowest section was 0·9in. in diameter, weighing 4¾lb. per lineal yard, and having a breaking strength of 24½ tons. The cables of the upper sections were correspondingly heavier. The stress on the cable in the lower section, with a fully-loaded car ascending, was 3,873lb. at starting and 3,942lb. at the end of the journey. A telephone wire was carried along the line, so that the conductor could signal to the engine-house from any point on the line. The cost of the line was £58,000, and the builders contracted to work it for the sum of £1,500 per annum, paying all expenses except renewal of cables and insurance of the passengers.

In an appendix statistics were given of a number of Swiss mountain railways, classified according to the methods in which they were operated.

THE ELECTRIC LIGHT AT THE MUNICIPAL OFFICES, BOMBAY.

The new Municipal Offices, Bombay, have been fitted up with the electric light on the alternating-current transformer system. The installation is of an ornamental type, as befitting the architectural surroundings.

We note, says the *Indian Engineer*, in passing, that the Bombay Municipality has been popularly credited with the announcement, made in broad daylight before the assembled members by one of the councillors, and supported by others, that the electric light is still in its infancy. As a result, we notice that, after spending several thousands of rupees on the installation of the electric light in the Municipal Offices, the councillors have decided to dispense with the services of an electrical engineer on the score of economy. Accordingly at the time we visited the offices, it was placed in charge of the superintendent of the municipal workshops. For the following information our acknowledgments are due to the chief engineer to the Bombay Municipality, Mr. M. M. Marzban, C.I.E., and to Mr. Hewett.

The Dynamos.—The principal dynamo is operated by an exciter, while both are driven by belting attached to suitable pulleys on the same shaft. The main dynamo is a compound-wound Thomson-Houston machine, capable of giving an alternating current at a pressure of 1,100 volts. The frame of the dynamo consists of two parts, horizontally secured by bolts; while the field wire is wound on 10 brass bobbins attached radially to the frame. There are two sets of wire coils, of thin and thick wire respectively, the sizes of which are selected to limit the loss below 5 per cent., the coils being grouped in series in each set. The bobbin frame is cast in a separate piece from the base, so that the former can be made to slide on the latter. The tension on the leather belt is regulated by means of a screw, attached to the base-plate, by which the bobbin frame could be shifted forwards or backwards. The armature revolves at the rate of 1,500 revolutions per minute. The foundations consist of wood and concrete, with bolts passing through. Stiff copper wire brushes are used, with the collectors, of which there are two sets, on the shaft of the armature, one set leading the direct current from the exciter dynamo into the field magnets; the other set supply current into the mains. The field coils are removable for repairs. The dynamo field is supplied by a part of its own current, which is returned through the commutator into the field coils, in addition to the current supplied by the exciter dynamo. The armature is hollow and well ventilated. The exciter dynamo is a Thomson compound-wound incandescent dynamo, of the single-horseshoe type, vertical. It is driven off a special pulley on the shaft which carries the pulley for the principal dynamo. The armature revolves 2,400 times per minute, and a pressure of 110 volts is attained at the terminals of the dynamo.

The Steam-Engine.—The motive power for the dynamos is supplied by a compound non-condensing stationary engine of 90 h.p., by Marshall, Sons, and Co., Limited, Gainsborough. The engine, which is of the underneath type, is combined with a locomotive multitubular boiler. It is erected on a wrought-iron frame, and is surmounted by the boiler. The fixing is thus of a simple character, and when the boiler is filled with water it tends to keep the entire structure rigid during work. The engine is fitted with patent automatic expansion gear, by which the steam is cut off at any desired point of the stroke at nearly boiler pressure, and is expanded to the utmost advantage. Uniformity in speed and economy in coal consumption are also secured. An outer bearing and standard with a fly-wheel are provided, as also an automatic sight-feed lubricator, a steam-trap for drawing cylinder jackets, etc. The power utilised at present comes up to about 65 h.p.

Accessories.—Thomson-Houston measuring instruments are used, the voltmeter being used with its own transformer. A special transformer is also provided with the pilot lamp in the dynamo-room to light the measuring instruments. An ammeter reading up to 40 amperes is used, the full-load current rate at present used being only about 25 amperes. The voltmeter is capable of reading up to 52 volts only, and is provided with a transformer which can convert the current pressure supplied to it from the dynamo to a pressure of 100 volts. The secondary coil of this is, however, constructed in two sections, which, being connected in parallel, the use of the low-reading voltmeter with it is possible. Rheostats and lightning arresters are fixed in the engine-room.

Underground Mains.—The main current at high pressure (1,100 volts) is conveyed by underground mains, passing along Palton-road and Hornby-road into the transformers in the Municipal Offices, a distance of about a quarter of a mile; indiarubber and lead-coated conductors are used for the purpose, led through cast-iron pipes, with draw-boxes about 100 yards apart.

Transformers.—The transformers are arranged, along with the measuring instruments of the Thomson-Houston type, in a room beneath the large staircase of the Municipal Offices, and are laid out in three sets, one for each flat. They convert the current from 1,100 to 100 volts. Thus, three main circuits in parallel run out of the transformer-room and enter.

Distributing Boards and Lamps.—There is one of the former on each flat. The lamps are incandescent lamps, varying between 16 c.p. and 50 c.p. each, of the Edison-Swan type. They are provided with the Edison-Swan patent contacts and bayonet joints, screw ribbon contacts being provided with the 50-c.p. lamps. Switches are attached to the main circuits, and one with each lamp, besides the double-pole main switch in the engine-room. Three ornamental chandeliers are suspended in the Council-hall, each containing 13 lamps of 50 c.p. each, with frosted glass covers.

Proposed Extensions.—For the present, the installation has been allowed to lie idle, as it has not been considered advisable to maintain a staff for the few hours' lighting required per week at the Municipal Offices. It is proposed, however, to light the Crawford Markets by making slight modifications and additions to the existing plant. We hope the extension work will be taken in hand early, to save the existing plant from deteriorating for want of use.

THE BRITISH CABLE—THE UNITED STATES AND HAWAII.

The *Times* of yesterday publishes a telegram from Washington stating that further official correspondence has been published regarding recent events in Hawaii. It supplements Admiral Walker's report, reveals differences of opinion between Admiral Walker and Mr. Willis, the United States Minister, and refers also to the endeavour made by the British Government, with the consent of the Hawaiian authorities, to secure the lease of an island in the Hawaiian group to be used as a cable station.

On October 13 Mr. Willis wrote to Mr. Gresham, Secretary of State, regarding the negotiations then proceeding between Hawaii and representatives of Great Britain with reference to the laying of a cable which should touch one of the islands. Mr. Willis said: "Mr. Sandford Fleming, the Canadian representative, and Mr. Mercer, of the British Colonial Office, accompanied by Mr. Hawes, the British Commissioner in Hawaii, have returned from Bird Island, which they have visited in the interests of the proposed cable. They will return by way of Washington, and will probably submit to the President and yourself some proposal. M. Verlaye, the French Commissioner, requests your attention to the possible extension of the French cable from New Caledonia to the United States, and he therefore hopes that the United States will not be hasty in arriving at a decision."

On December 3 Mr. Willis again wrote to Mr. Gresham as follows: "In Hawaiian opinion, Hawaii is estopped from considering the proposal of the British Commissioners by the reciprocity treaty with the United States. . . . . This matter is, therefore, at the request of Hawaii, submitted to the consideration of the United States upon the question of the willingness of the latter to modify the reciprocity treaty by exempting an island from the operation of the clause preventing any special privilege being granted to another Power."

Digitized by Google

Mr. Willis encloses a note from Mr. Hatch, Hawaiian Minister for Foreign Affairs, expatiating on the importance of the cable to Hawaii, and saying that the opportunity was one to which Hawaii could not be indifferent, if it could be taken up consistently with treaty obligations, and no scheme more desirable were presented. Mr. Hatch proceeded to say that as the proposal was one in which Great Britain was directly or indirectly interested, Hawaii felt estopped by the reciprocity treaty from considering it until the views of the United States had been ascertained. Mr. Hatch enclosed a letter from Mr. Sandford Fleming and Mr. Mercer transmitting copy of the memorandum of agreement, and stating that they presumed that Mr. Hatch would bring the proposed arrangement to the notice of the United States and ascertain whether the latter would give their consent.

Mr. Fleming and Mr. Mercer, moreover, pointed out the advantages accruing to the United States from the proposed cable. They observed that it was by no means a settled undertaking to be carried out as a Government enterprise, but that it might be committed to a company whose lease would not literally come within the terms of the treaty. Having regard, however, to the circumstance that foreign Governments would have a substantial interest in the lease, the British and Canadian Commissioners quite agreed with the suggestion that the agreement in any shape should have the sanction of the United States. The subsidy demanded was £7,000 per annum for a period of 15 years.

The above correspondence was sent to Congress on Wednesday, with a message from President Cleveland, in which the latter says: "I submit herewith certain despatches from our Minister in Hawaii and the accompanying documents. They disclose that Hawaii desires to lease to Great Britain one of the uninhabited islands as a station for a submarine telegraph cable between Canada and Australia, with connection between the island leased and Honolulu. Both Hawaii and the representatives of Great Britain in the negotiations concede that the proposed lease cannot be effected without the consent of the United States owing to our reciprocity treaty with the king. The latter agreed that as long as the treaty remained in force he would not lease, otherwise dispose of, or create a lien upon any port, harbour, or other territory in his dominion, or grant any special privilege or right of use therein to any other Power, State, or Government. At the request of Hawaii this subject is laid before Congress for its determination upon the question of so modifying the treaty as to permit of the proposed lease. It will be seen that the correspondence between Hawaii and the British negotiators negatives the existence on the part of Hawaii of any suspicion of British unfriendliness or fear of British aggression. The attention of Congress is directed to the following statement contained in the communication addressed to Hawaii by the representatives of Great Britain: 'We propose to inform the British Government of your enquiry whether they would accept the sovereignty of Neckar Island, or of some other uninhabited island, on condition that no subsidy be required from you. As we have explained, we have not felt at liberty to entertain that question ourselves, as we were definitely instructed not to ask for the sovereignty of any island, but only of a lease simply for the purpose of the cable.' I hope Congress will see fit to grant the request of Hawaii, and that our consent to the proposed lease will be promptly accorded. It seems to me we ought not, by a refusal of this request, to stand in the way of the advantages to be gained by isolated Hawaii through telegraphic communication with the rest of the world, especially in view of the fact that our own communication with that country would thereby be so greatly improved without apparent detriment to any legitimate American interest."

WORK OF AN ELECTRIC CURRENT.

At the Royal Institution on Thursday afternoon of last week Prof. J. A. Fleming, F.R.S., gave the fourth of his Christmas lectures on "The Work of an Electric Current." Before dealing with the proper subject of the day's lecture, which was the current working as an illuminator, he performed some additional experiments in illustration of the current's heating effects. He first demonstrated the curious properties, discovered by Peltier, which are possessed by a certain form of bismuth-antimony junction. A current passed through it in one direction develops heat, in the other cold; while, reversely, the application of a piece of ice to it produces a current. It is also capable of acting, to a slight extent, like a secondary battery, for after being subjected to a current for a short time it is able in turn to give one off. The utilisation of the heating effects of the current in the construction of instruments for the detection of minute electric currents was explained. A narrow strip of platinoid, twisted and fixed at its ends, will untwist slightly when a current is passing through it, and its movement may be observed by appropriate means. Prof. Fleming then passed to the consideration of the illuminating powers of the current. These, he said, may be obtained in two ways—either by heating a conductor by a current to incandescence, or from the electric discharge taking place through gaseous non-conductors. The discharge in the latter case assumes four forms; it may appear as a spark, a brush, a glow, or an arc. A spark was described as the light and heat produced when the strain in the non-conducting air between two oppositely-charged conductors becomes greater than it can support. No strain, and therefore no spark, can occur unless there is electric pressure, and so Prof. Fleming digressed to explain the Wimshurst machine, which generates a very minute current of electricity at very high pressure. He emphasised the fact that the current given off by this machine (of which a very large specimen, with six pairs of plates, was exhibited) is identical in kind with that obtained from a voltaic cell. The difference between the two he described as analogous to that between a large quantity of water falling from a small height and a little water falling from a great height, the current from the machine corresponding with the latter. He then pointed out the shortness of the duration of the spark discharge, and described the revolving mirror apparatus employed by Sir Charles Wheatstone to measure it. Increasing knowledge, however, he said, has proved that the duration depends on a variety of circumstances, and it is impossible to assign any particular length of duration to the spark in general. He produced a splendid display of long sparks, in illustration of the disruptive power of the discharge, by connecting the terminals of the machine to two tall glass vessels lined with tin foil and standing on a sheet of gold foil. The brush discharge was next considered, and it was shown that when two charged conductors are more widely separated than is necessary for the spark discharge the air space between them is filled with a rosy-purple light. The effect appears continuous, but really is not so; it is supposed to be caused by the alternate charge and discharge of the particles of air. The glow produced by discharge in a rarefied atmosphere was next shown, and the phenomenon of fluorescence exhibited by means of uranium glass. The stratified discharge was shown in tubes containing minute quantities of hydrogen, turpentine, and sulphuretted hydrogen respectively, and the wind given off by a pointed conductor was used to blow out a candle. Prof. Fleming then dealt with the arc discharge, which, he remarked, was first obtained by Davy in the Royal Institution, and images of the arcs made between iron and carbon points were thrown on the screen. After briefly explaining the conditions necessary to the production of this form of discharge, the lecturer passed on to consider the other way of obtaining light from electricity by using it to heat a conductor to incandescence, and concluded with a short description of the manufacture of the incandescent lamp.

The fifth of Prof. J. A. Fleming's Christmas lectures on "The Work of an Electric Current" was delivered on Saturday afternoon, and was devoted to the consideration of the current working as a messenger. Prof. Fleming began by stating the elementary facts upon which depends the action of the electric telegraph, and passed in review some of the principal types of instrument now employed. He mentioned Oersted's discovery of the influence exercised on a movable magnetic needle by the passage of a current in a neighbouring conductor, and showed that a bar of iron is magnetised when a current is sent through a coil of wire wound round it, the intensity of effect produced varying with the quantity of wire in the coil. By experiment it was proved how quickly the iron, if pure, becomes demagnetised when the current is stopped, and to illustrate this fact the construction and action of an electric bell were explained. The single-needle telegraph instrument, together with the older form having five needles, was then described, and consideration of the complexity of the latter suggested the remark that it seems to be a law of invention that simple methods of attaining a given end usually result from the progressive improvement of others more difficult and complicated. An explanation of the combinations of right and left beats of the needle, and of dots and dashes, to denote the different letters of the alphabet was followed by a brief account of the Morse printer and sounder. The next instrument discussed was the mirror galvanometer, devised by Lord Kelvin for use with the short-lived Atlantic cable of 1858. Prof. Fleming gave directions by which for a few pence a home-made mirror galvanometer might be constructed which would give results practically as good as those obtained from an expensive instrument made by a first-class maker, and explained how to make a battery for use with it out of a tin can, some iron filings, a porous pot, a piece of zinc, and some washing soda. He then described Kelvin's syphon recorder as employed on almost every long ocean telegraph, and, returning to land-line instruments, dealt with the Wheatstone automatic transmitter, by the use of which the report of a big speech may be simultaneous despatched from one centre to the newspapers in a dozen or more towns. He mentioned that when Mr. Preece was put in charge of the postal telegraphs the average speed of these transmitters was about 80 words a minute, while

Digitized by Google

now they are worked up to 600. The lecture concluded with an explanation and exhibition of Gray's telautograph, which does not transmit the signals of a code, but reproduces on its receiver a facsimile of the writing traced at the sending station. Even sketches can be sent through it, and it has been successfully worked over the telephone cable between Paris and London. By the kindness of the postal authorities a couple of their operators were present to show the working of the various telegraphs described by the lecturer, the instruments employed being also lent by the Post Office.

The sixth and last of Prof. J. A. Fleming's Christmas lectures was delivered on Tuesday. After mentioning the ingenious typewriting telegraph invented by Prof. Hughes, which has the advantage of requiring on an average only a third of the number of currents necessary for the Morse instrument, he made a few remarks about the telephone. He first explained Ohm's law of the relation between current, E.M F., and resistance, and then showed the experiment with which was closely connected the invention of the microphone by Hughes. If a number of plates of carbon are piled one on the other, the electrical resistance of the pile is diminished when the plates are pressed together, and increased when the pressure is removed. The microphone essentially consists of a piece of carbon resting lightly on another piece, and it is found that the electrical resistance of such an arrangement is sensibly affected by the slight changes in the pressure upon it caused by the air-waves which are set up by the speaking voice. It can, therefore, be used as the transmitter of a telephone. The receiver is constructed by taking advantage of the fact that the strength of an electromagnet varies with the current circulating in its coils. If a thin iron plate be fixed in front of a permanent magnet wound with wire like an electromagnet, and if the current flowing in the wire be passed through a microphone, the attraction on the iron plate will vary exactly with the variations of pressure sustained by the microphone, and therefore the iron plate will move and set up the same vibrations in the air as were present in the air surrounding the microphone. Prof. Fleming then passed to the consideration of the current working as a force. He first showed Faraday's experiment of the production of a current by rotating a copper disc between the poles of a magnet. He used Faraday's own machine, and exhorted his audience to regard it with reverence, for on it was performed the fundamental experiment which led to the construction of all the machines now used for the transformation of mechanical power into electricity. He then drew attention to the broad principle that whatever physical process can produce a current can reversely be produced by a current, and in illustration showed how Faraday's experiment can be reversed and a copper disc made to rotate by passing a current round the magnet. This last experiment he described as being the progenitor of the motor, just as the other one was of the dynamo. He then briefly traced the development of the dynamo. The first improvement was the substitution of bobbins of wire for the copper disc, and the next the multiplication of the bobbins and magnets as in the Alliance magneto-machine, which is not yet obsolete, since it is used, among other places, at the lighthouse on St. Catherine's Point, in the Isle of Wight. The next improvement was made by Siemens, who altered the form of the bobbin, and wound it on a different plan; he was also able to design his machine so as to utilise more of the magnetic field than had hitherto been done. About 1866 Varley and Siemens almost simultaneously made the discovery that electromagnets, excited by the current produced by the machine itself, can be used in place of permanent ones, and this, together with the invention in 1870 of Gramme's ring, a new and more efficient form of armature, was the foundation of modern dynamo construction. As regards the development of the electric motor, Prof. Fleming said that 20 or 25 years ago it became clear to electricians that the dynamo is a reversible machine—that is, can either be used to transform motion into electricity or electricity into motion. Attempts had been made to construct motors which depended for their action on the attraction and repulsion of magnetic poles. Such motors, indeed, moved, but they were very inefficient, and could do no work, resembling an idle boy who eats a great deal but does very little for his food. Prof. Fleming was very particular to point out that motors, as now constructed, are practically reversed dynamos, and that the amount of energy they consume varies strictly as the work they have to do. Engineers, he said, are beginning to see the advantages of electrical distribution of power, and quite lately he visited an engineering shop every tool in which was driven by a separate electric motor. Some photographs were shown on the screen illustrating the employment of electricity for such purposes as traction and hoisting. Prof. Fleming then spoke of the long-distance transmission of electricity by alternating currents, which differ from continuous ones something in the way a tidal river with its ebb and flow differs from a non-tidal one, and showed an alternating-current motor in action. This was unable to start itself, but when once it was started and had "got into step" with the dynamo at Deptford (seven or eight miles away) which supplied the current it would continue to run at the same speed as the dynamo, unless so heavy a load were put upon it as to cause it to slow and get out of "step." In conclusion, the lecturer made a few remarks on the nature of the electric current. The question, What is electricity? is a natural one to ask, but one which does not admit of a short and direct answer. A high place must be given to the discovery, which, if not absolutely demonstrated, is most probably true, that space is not empty, but filled with a something which has been called ether. There is abundant proof that light is due to a series of changes in this ether. We do not know the nature of these changes and are not justified in calling them motions, but we may regard them as very short waves. Faraday held the opinion that electricity depends on analogous changes in a medium or ether, and Clerk Maxwell elaborated the theory, while Hertz, who only died last year, invented what may be called an electromagnetic eye which can detect long waves, several yards in length, just as our eye detects short waves. The existence of this electromagnetic medium must be regarded as highly probable. Prof. Fleming then thanked those who had assisted him in his lectures and had lent him apparatus, and hoped that some of his hearers might be attracted to the further study, and especially experimental study, of electricity, promising them that they would thus open up to themselves a boundless region of pure and permanent pleasure.—*The Times.*

THE EXPLOSION IN EUSTON ROAD.

An enquiry was held at the St. Pancras Vestry Hall yesterday by Major P. Cardew, on behalf of the Board of Trade, into the explosion which took place at midnight on December 29 in the Euston-road, to which we referred last week. Prof. Robinson was present on behalf of the Vestry; Messrs. Bassett Hopkins and Gunyon on behalf of the London County Council; and Mr. Foulger on behalf of the Gaslight and Coke Company.

The first witness called was **Police-Constable James Diprose.** He stated that on the night in question, while at the corner of Endsleigh-gardens and Gower place, he heard an explosion in the Euston-road, and just on arriving there a second explosion took place. He saw three or four of the flagstones at the electric manhole fly into the air to a height of about 20ft. He saw no flame, but there was dense smoke. Turning along the Euston-road about a distance of 20 yards, he found the cover of a manhole displaced and lying about 8ft. from the manhole. It was not broken. About 45 yards of the pavement were raised. He then informed the electric light department and the gas company. Two men named Petrie and Govier informed him that they had been hurt. There was a smell of coal gas at the corner manhole.

In reply to **Mr. Gunyon**, he said that what he took to be flagstones in the air was probably the cover of the manhole.

Mr. Charles Govier said that while coming along the Euston-road from Gower-street with his friend Petrie he saw a flash and was hurled into the air, coming down on his back. Then the ground heaved up and he was thrown into the gutter. He did not see a second flame. On getting on to his legs again he found Petrie, who said he felt dazed, holding on to the railing. With assistance they walked to University College Hospital, where his side was strapped up. He had sustained a shock to the system, and still felt pain. He had not smelt any gas.

Mr. Edward Pycraft, chief clerk of the St. Pancras electric and public lighting department, said that on behalf of the Vestry he had called at the hospital to enquire into the cases referred to. The house-surgeon's report was that Govier had a bruised side and Petrie a sprained ankle. Both of them were stated to be mild cases.

Mr. James Thomas Baron, chief engineer of the St. Pancras electric light station, stated that he had under him Mr. Thomas, an outdoor inspector, who reported to him the result of his inspections. The manholes were inspected about once in four to six days, both for water and for gas, the gas being traced by smell. Both the manholes relating to the explosion had been inspected the day previous to the event. The presence of gas in the culverts had been a source of trouble for some time past, and where smells had been observed more frequent inspections were made. The gas which was perceived was coal gas. The manholes were drained into and trapped from the sewers. At one of the manholes in question no gas had been traced since July last, but at the second, gas had been found on November 15 and December 13 last. The Gaslight and Coke Company were written to on December 14 that the culvert was highly charged with gas, and asking that attention should be paid to the matter. The gas company did not reply to the letter, but he heard that their men had opened the ground on December 14. On the night of the explosion he was told of the occurrence by a policeman, and he reached the spot about a quarter of an hour afterwards. He found a length of about 30 yards of the pavement raised from 2in. to 3in. He noticed a smell of coal gas at one of the manholes. The two manholes, which were 10 yards apart, were connected by an 8in. iron pipe, containing three strips of bare copper wire supported on porcelain insulators, this method being adopted in certain places

Digitized by Google

where other pipes had to be crossed. After the explosion he examined the copper strips, and found them in good condition. There was no electrolysis. The insulators had been displaced by the force of the explosion. The fuses, consisting of tin strip, had not been affected. The brickwork of one manhole was much shaken, and the cover of iron, filled in with York stone, was broken. The cover of the other manhole was displaced. On the morning of Sunday, December 30, he, in company with Mr. Man, of the gas company, inspected the manholes in the vicinity. There was no gas, but the manholes had been open. At the one manhole there was on the negative side insulator a slight incrustation. This had been analysed, and consisted of a salt with a slight proportion of caustic soda. They frequently found incrustations in the manholes, but none in the culverts. The copper strips were in as good condition as when laid down. There were about 6½ miles of mains on the culvert system. Up-cast pipes had been put in after the Endsleigh-gardens explosion of January 12, 1894. There used to be pilot wires in the culverts, but these had been removed. There were 11 ventilating pipes in all, and three ventilating covers to manholes. The inspection tubes in the manhole covers also acted as ventilators. This work had been carried out on the recommendation of Major Cardew after the explosion of a year ago. With respect to his recommendation to have wooden shields in the chambers, such had been fixed in many cases, but they got wet, swelled, and broke away. As regarded the recommendation to substitute two small chambers for one large one, there had been a practical difficulty in the way. When they found the insulation of the negative low, they took steps to clean the insulators.

In reply to **Mr. Bassett Hopkins**, the **Witness** said there had not been any short-circuit There was certainly coal gas there, and there might have been a spark.

In reply to **Mr. Foulger**, he said that the gas company had attended to the complaint by sendnig men. The conductors were fairly light, and separated by distance-pieces at intervals of about 3ft. The mains certainly could not have come into contact with each other, for if they had the fuses would have been blown out, and they had not done so. He had, however, known of one case, about 18 months ago, where mains had touched, though he did not know the cause There could not have been any hydrogen gas produced by electrolysis of the moisture. He had smelled coal gas since the explosion. He had heard that the gas company's officials had been testing daily and not found traces of gas. The incrustration on the negative insulator might have had something to do with the matter.

Mr. William John Thomas, outdoor inspector of the electric light department, stated that he had charge of the mains and house connections. He desired to correct Mr. Baron in regard to two points: firstly, the manholes were inspected at least once in three days, and, secondly, there were four ventilating covers, not three. He had noticed a strong smell of coal gas at a manhole 43 yards away from one of those where the explosion occurred. On December 31 he smelled gas, and drew the attention of Mr. Gunyon and Mr. Champion, officials of the London County Council, to the fact. On December 13 one of his men reported a smell of gas. He did not consider the gas detector used by the gas company as an efficient instrument. On December 30 he tested the section in question, which gave a low insulation, but he had known it as low before. In his opinion the ventilation was not sufficient to get rid of the coal gas, which was their greatest danger.

Mr. Foulger suggested that the smell which had been noticed was due to the smell of the gas-main in the neighbourhood and not to coal gas itself.

Prof. Robinson pointed out that if this were the case, the smell would be constant and not intermittent.

Mr. Edward Bennion, electrical jointer and foreman under Mr. Thomas, had examined the fuses and found them all right. He had smelled gas after the explosion. The following morning he went with Mr. Man, of the gas company, and the gas detector was put down, but did not move. It was also put down over a gas jet with the tap turned full on, and it did not move till after a lapse of three to four minutes. He agreed with Mr. Thomas as to the inefficiency of the detector.

Mr. William Nisbett Blair, borough engineer and surveyor to the Vestry, owing to the suggestion that sewer gas might have something to do with the explosion, had examined the sewer and found the air unusually free from smell. At an electric manhole in the neighbourhood he had found a smell of coal gas in the presence of one of the gas company's men, but the instrument failed to move. Sewer gas *per se* was not explosive, but he had known explosions take place in sewers owing to the presence of coal gas. His men worked in the sewers with naked lights.

In reply to **Mr. Foulger**, he said he could tell the difference between the smell of coal gas and the waste products from an indiarubber works. Besides, there was no rubber factory in the parish.

Mr. G. F. L. Foulger, engineer to the Gaslight and Coke Company, stated that the whole of the tests they had applied failed to show the presence of gas anywhere near the locality. He was present out of respect to the Board of Trade, and not because his company admitted any liability in the matter.

In reply to **Prof Robinson**, he said that gas unaccounted for amounted to 4 per cent., but he thought that actual leakage amounted to only 1¼ per cent. He attributed the explosion to an accumulation of hydrogen gas evolved by electrolysed moisture on the insulators, and that this had been exploded by sparking.

Major Cardew pointed out that in such an event there would have been corrosion on the conductors, which was not the case.

Prof. Robinson said that he had advised the Vestry to supplement the present ventilation by a more thorough system which would avoid any future explosions of gas.

The enquiry then terminated.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Saint-Die (Vosges, France).—The Municipality invite tenders by February 1 for the concession for a central electric light station for the town.

Stockport.—Tenders are invited for providing and fixing complete a fuel economiser, for the Corporation. We have already given particulars. Tenders are to be delivered by 16th inst.

Louvain (Belgium)—Tenders are invited by February 1 by the local authorities at the Hotel de Ville for a concession for an electric tramway from the railway station to the Grand Place, Louvain.

Nelson.—Tenders are invited for lighting Stanley-street Chapel, Nelson, with electricity. Particulars are obtainable from Mr. James Bateson, 10, Primrose-street, Nelson, to whom tenders are to be sent by the 18th inst.

Birmingham.—The committee of the Birmingham Municipal Technical School invite tenders for the installation of the generating plant, etc., in the new school. Particulars have already appeared in our pages. All tenders must be sent in to Mr. Geo. Mellor, secretary, by to-morrow.

Ludlow.—The Corporation require tenders for providing a means of automatically indicating in the town the depth of water in the reservoir, situate on a hill about 800 yards distant. Full particulars can be obtained from the borough surveyor. Tenders are to be sent to Mr. Williams, the town clerk, by the 18th inst.

Nottingham.—Tenders are invited for the supply of lamps, lamp columns, etc. Further particulars and forms of tender may be obtained of Mr. Rhodes, lighting inspector, St. John's-street. Tenders to be sent to Sir Samuel G. Johnson, town clerk, Guildhall, Nottingham, by 11th inst., endorsed "Tender for Lighting Requisites."

Bristol.—Tenders are invited for the installation of the electric light at the Guildhall and a portion of the Council House, for the Corporation. Plans may be seen at the office of the city electrical engineer, Mr. H. Faraday Proctor, A.M.I.C.E., M.I.E.E, Temple-back, from whom specifications may be obtained. Tenders to be sent to the chairman of the Finance Committee, the Council House, Bristol, by January 18, endorsed "Tender for Electric Light Installation."

London.—The Metropolitan Asylums Board, as will be seen from our advertisement columns, invite tenders for the supply and running of mains, and the wiring of the buildings and grounds of the North-Western Fever Hospital, Haverstock-hill. A copy of the conditions of contract and specification may be purchased at the offices of the Board, Norfolk House, Norfolk-street, Strand, London, W.C., and the plans can be seen at the hospital. Tenders are to be delivered at the offices of the Board not later than Thursday, the 24th inst.

RESULTS OF TENDERS.

Stafford.—The Town Council have accepted the tender of the Electric Storage Syndicate for the construction of the accumulators at a cost of £822, and one of £524. 18s. from the Electric Construction Company (Wolverhampton).

Aberdeen.—The Finance Committee of the Town Council have provisionally accepted the offer of Messrs. New and Mayne to furnish the wiring for the electric light in the Municipal Buildings. The Corporation's engineer will erect the fittings.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,253.

Great Northern Telegraph Company.—For the month of December the receipts were £24,800.

Fleetwood.—The Urban District Council have met in committee to consider the electric lighting question.

Rottingdean.—A scheme is on foot for the electric lighting of Rottingdean, with an extension of mains to Ovingdean.

Harrow.—Messrs. Crompton and Hawtayne have purchased the electric lighting provisional order obtained by the Harrow Local Board.

Dublin United Tramways Company.—The Board have declared a dividend at the rate of 5 per cent. per annum for the latter half of 1894.

Eastern Telegraph Company.—The receipts for the month of December were £55,593, as against £55,579 for the corresponding period of 1893.

Direct Spanish Telegraph Company.—For the month of December the receipts were £1,671, as against £1,895 for the same period of 1893.

Carnarvon.—Mr. Issard Davies said at a recent meeting of the Town Council that if they could not get better gas they had better introduce the electric light.

Digitized by Google

Eastern Extension Telegraph Company.—For the month of December the receipts show an increase of £2,877 as compared with the corresponding period of 1893.

Burnley.—The Town Council have decided to increase the remuneration of Mr. F. Thursfield, the municipal electrical engineer, from £150 to £200 per annum.

Windermere.—The Urban District Council have appointed Messrs. Garnett, Fell, Irving, and Latham to deal with the electric lighting company's application for a provisional order.

City and South London Railway.—The receipts of the Company for the week ended January 6 were £1,004, against £990 for the corresponding week of 1894, or an increase of £14.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 6th inst. amounted to £926, as compared with £688 in the corresponding week of last year.

Surbiton.—The Electric Light Committee appointed by the Urban District Council consists of Messrs. Gibbes, Thynne, Marshall, Lapage, Judd, and the chairman (Mr. Guildford).

Weston-super-Mare.—The new members of the Lighting Committee of the Urban District Council are Councillors Boyden, Phillips, Heap, Deverell, Gill, Ball, Dubin, Clark, and Bryant.

Canterbury.—The Town Clerk has informed the Town Council that nothing has been heard from the Brush Electrical Engineering Company withdrawing their claim to the electric lighting order.

Salisbury.—The Town Clerk has informed the Town Council that he has received two copies of the electric lighting company's license as finally issued by the Board of Trade. It is practically what the Council have already approved.

Technical Institute Lighting.—The order for the electric lighting of the new county technical instruction buildings, Stafford, has been placed with Messrs. Drake and Gorham, of London, who are to put in about 300 lights.

Eastern Extension, Australasia, and China Telegraph Company.—The interest on the 4 per cent. mortgage debenture stock for the half-year ending January 31 will be paid by warrant on February 1. The stock register will be closed from 28th to 31st inst.

Taunton.—The Electric Lighting Committee reported to the Town Council on Tuesday that the Local Government Board had sanctioned the borrowing of £5,000 for purposes of electric lighting. The works in connection with No. 2 sub-station would be proceeded with at once.

Blackpool.—More arc lamps are being suggested for Claremont Ward. The attention of the Electric Lighting Committee has been called to the bad state of Bolton, Church, and Rawcliffe streets, South Shore, caused by the laying of the electric light mains in those thoroughfares.

Poyle Mills Company, Limited.—This Company has been registered with a capital of £2,000 to enter into an agreement for the acquisition of the business of a manufacturer of asbestos goods, now carried on by T. H. Ibbotson, under the style of the Poyle Mills Company, at Poyle, Middlesex.

Eton.—The scheme for applying for an order from the Board of Trade by the Windsor Corporation for the supply of electricity to Windsor and Eton, has been brought forward before the Eton Urban District Council, and the whole of the particulars were laid upon the table. The subject was postponed.

Supper.—The fourth annual supper of the employés of the Birmingham electric tramway route, Bristol-road, was held on Thursday last week at the Bournbrook Hotel. Mr. J. Booth, one of the directors of the Birmingham Central Tramway Company, presided over a gathering of nearly 100 employés.

Elmore Copper Companies.—These companies have been officially notified that their names have been placed upon the list of contractors to her Majesty's India Office for the supply of copper tubes, copper cylinders, and copper tape such as is used in the manufacture of cartridge-cases and for electrical purposes.

New Telephone Company.—An extraordinary general meeting of the New Telephone Company, Limited, held last week at the offices, London-wall, confirmed the resolution passed at the extraordinary general meeting held on the 19th ult. for winding up the the Company voluntarily. Mr. Albert Anns was appointed liquidator.

Lister Electric Light and Power Company.—Mr. W. J. Lister of Rivers Mills, Dursley, Gloucestershire, informs us that he has started, in addition to his own engineering and iron foundry trade, a branch business, the title of which is the Lister Electric Light and Power Manufacturing Company. The address is the same as above.

Bolton.—Alderman Miles, in proposing the minutes of the Gas and Electricity Committee, called attention to the fact that many persons had not replied to the circulars issued by the committee with reference to the supply of electricity, and intimated that every information as to cost, etc., might be obtained from the engineer.

Morecambe.—The Morecambe Electric Light and Power Company, Limited, have decided to remove their works from their present position in Edward-street to a site removed from the residential part of the town. It will be remembered that complaints have been made that the company's use of water gas constituted a nuisance.

St. Pancras.—The following have been elected members of the Electricity Committee: Messrs. Boden, H. Davies, Menzies, Prosser, Creed, C. H. Gittens, Thomson, Close, Cox, Guerrier, Parkes, Boulting, W. Smith, Williams, H. Cooper, Parkyn, Sweet, Hodgkinson, Ives, King, Catesby, Pettit, Rutter, Dean, Matthews, and Vickers.

Ripon.—The Mayor, Mr. Baynes, in referring to the subject of the gasworks, stated that in five years the whole debt on the capital account (originally £18,000) would be paid off. Then would be the time to go in for the electric light, unless there was such an improvement in the production of gas as to enable it to compete with the electric light.

Warminster.—The new Urban District Council has held a meeting at which the Clerk stated that the Local Government Board had declined to sanction the application for a loan for the electric light until the Council had obtained a license from the Board of Trade to produce electricity. It was then decided to take the necessary steps to obtain a license.

Worthing.—A meeting of the Town Council has been held, at which Alderman Cortis commented upon the action of the Highways Committee in encouraging experiments for the improvement of the street gas lighting, and urged the undesirability of spending money in this direction, if, in the near future, the Council were determined on having the electric light.

Larne.—The Town Commissioners received on Monday a letter from the electric company stating that the county surveyor obtained a decree at the Ballymena Quarter Sessions compelling them to remove the lamp-post at the corner of Inver and Bank roads. The receiver and manager of the electric company wrote requesting payment of the half-year's lighting account.

Maidstone.—A meeting has been held of the Urban District Council in connection with which Mr. Councillor Morling had given notice to move, "That this Council endeavour to dispose of the electric lighting order by tender, the conditions to be settled by the Electric Lighting Committee"; but as nearly all the members had left when the matter came up, he decided to defer the question till the next meeting.

Wells.—The Town Council on Monday had before them a letter from Messrs. Davies and Roach, agents of Mr. Brown, electrical engineer. They stated that they were in communication with the Board of Trade, who wrote that, while not declining to issue a license for electric lighting, they were prepared to grant a provisional order if applied for. The matter was deferred by the Council until the draft of the agreement with Mr. Brown for electric lighting is before them.

Smoke and Fumes Annihilator Company—This Company has been constituted with a capital of £120,000 in £5 shares to acquire the British patents of Mr. Samuel Elliott's invention, together with the trade marks and goodwill of the vendor relating to the sale of the disinfectant produced therefrom, and to manufacture, sell, and let on hire smoke annihilators, etc. The number of shares offered to the public is 18,000, the list of applications opening on Saturday and closing on or before Tuesday next.

Leicester.—The first place of worship in Leicester to adopt the new illuminant supplied by the Corporation from their gas and electric lighting department has been the Bishop-street Wesleyan Chapel, where an installation costing about £160 has been completed. Previously the chapel was lighted by 137 gas burners, and for these 134 16-c.p. incandescent electric lamps have been substituted. The work has been carried out by the Corporation, under the personal supervision of their engineer, Mr. Colson.

Hertford.—The following resolution has been passed by the Hertford Town Council: "That the requisite plans and specifications for the electric light installation in Hertford, prepared by Mr. J. A. McMullen, M.I.E.E., be laid before the Brush Electrical Engineering Company, in order that this company may tender for carrying out the same, with a view to the said company working the installation for a period and upon terms to be agreed upon between the Corporation and the said company."

Llanelly.—The new Town Hall and the new market hall at Llanelly will be shortly approaching completion, and one of the last things done by the old Local Board was to instruct the surveyor to report upon the probable cost of introducing the electric light to take the place of gas. The surveyor has reported that unless some of the tradesmen in the town also agree to go in for the new illuminant, a scheme for its introduction could not be carried out. Circulars have now been addressed to the principal tradesmen asking them whether they are prepared to adopt the change.

The Electrophone, Limited.—This Company has been formed, with a capital of £20,000 in 4,000 shares of £5 each, to take over and develop the business of the Electrophone Syndicate, which has for the past two years obtained patents, contracts, and concessions. The purchase price of the property, etc., for the whole of the United Kingdom has been fixed by the contract between the vendors and the Company at £15,000, payable as to £7,750 in fully-paid shares of the Company, as to £2,250 in cash, and the balance in cash or shares at the option of the directors, so that £5,000 will be available for working capital.

Belfast.—Alderman Pirrie, at a meeting of the Town Council, moved the adoption of the Electric Committee's report, which stated that considerable progress had been made with the central station and street works, and the committee anticipated being in a position to supply the electric light in the present month. Alderman Pirrie said that he felt great pleasure in announcing that they hoped during this month to have the electric light at the disposal of those who requested it. Considering that the committee was only appointed that day 12 months, and that they had now practically completed the works, he thought the result was very satisfactory. The report was adopted.

Digitized by Google

City.—At this week's meeting of the City Commission of Sewers Mr. Johnson asked if the Streets Committee had considered the question as to the possible reduction in the cost of the public lighting of the streets. Mr. Burmester replied that certain experiments were being made in a system differing from the arc lighting, and the members hoped they might prove successful and prove better than the present system. Mr. Johnson asked if it was true that there would be a probable reduction of one or two thousand pounds a year. Mr. Burmester said he did not know whether that was so or not.—The electric light at Skinners' Hall, Dowgate-hill, has been installed by Messrs. Rashleigh Phipps and Co.

Long-Distance Telephony.—A meeting has been held of the Luton Chamber of Commerce, at which the President said their application in regard to telephonic communication with London they had every reason to believe had received proper attention If the Government simply took over the trunk lines connecting Liverpool, Manchester, Birmingham, and Hull with London, and left the rest of the country out in the cold, he did not know where they would be. He thought it was very probable they would have an opportunity shortly of speaking with their friends in London as much as other large centres had. Mr. Smith said the Government anticipated putting an exchange at Luton.

Windsor.—It is only a few months ago that the Windsor Electric Installation Company secured premises in High-street, and the services of Mr. E. A. Farrow as their manager, yet they have already completed a number of installations in the town and neighbourhood, and have also several large prospective contracts on hand. Their premises, at 48, High-street, are fitted up with a complete generating plant, consisting of a 6-h.p. Stockport gas-engine. driving a dynamo. Acting as a kind of central station, the Windsor Electric Installation Company has undertaken the lighting of the ground floor of Messrs. Caley and Son's establishment with 32-c.p. lamps. Other tradesmen have also adopted the light.

Electric Construction Company, Limited.—The staff and employés of this Company were entertained at dinner by Sir Daniel Cooper, Bart., G.C.M.G., chairman of the Company, in the Victoria Hotel, Wolverhampton, on Saturday last. Upwards of 120 gentlemen were present. The chair was occupied by Mr. James W. Barclay, in the unavoidable absence of Sir Daniel Cooper. After dinner, the following toasts were proposed and duly responded to: "The Queen and Royal Family," "Success to the Company," "Mr. Blackburn, the Staff, and Employés," "Sir Daniel Cooper, Bart," and "The Directors." During the evening, an address was presented to Mr. E. Garcke on the occasion of the expiry of his agreement as managing director of the Company.

Lambeth.—Mr. N. W. Hubbard, at the first meeting of the new Vestry, proposed the election of a Special Electric Lighting Committee. This might not be an opportune moment for installing the electric light, but at the same time he thought the Vestry should be put in possession of the latest information on the subject He was of opinion that the Vestry should not stand in the way of the users of the electric light. Mr. J. E. S. King seconded, as he believed the Vestry should be up to date in regard to the electric lighting system. Mr. Graves thought the matter was too important to be dealt with that night, and moved the adjournment of the question until next meeting. Mr. Victor Roger seconded the amendment, which Mr. Hubbard accepted, and the Vestry agreed.

Portsmouth.—The Electric Lighting Committee recommended that they be authorised to extend the electric light mains through Arundel-street (on one side), through Marmion-road (on both sides), as far as the Southsea Dairy Company's premises through Castle-road (on one side), and through Lake-road, and St. Mary's-road to the infectious diseases hospital; and that application be made to the Local Government Board for their sanction to borrow £3 056, the total estimated cost. This sum would, in fact, be part of the £20 000 which had already been sanctioned, but although an enquiry had been held as to this amount, a separate application was required as to each amount desired to be borrowed. After some discussion, the report of the committee was adopted.

Appointments Vacant.—The Technical Instruction Committee of the East Suffolk County Council invite applications for the office of organising secretary. Salary £200 per annum, and, in addition, actual travelling and out of pocket expenses. An office and a clerk are provided. Applications, stating qualifications, and enclosing copies of not more than three testimonials, to be sent to the secretary of the committee, Mr. D. T. Cowan, 26, Butter Market, Ipswich, by 11th inst. The appointment will be subject to confirmation by the County Council at the meeting in March. The candidate selected is required to enter upon his duties on February 1. Canvassing will be considered a disqualification.—An assistant electrical engineer is required at a salary of £120 by the Corporation of Sunderland.

Cardiff.—There are now about 30 private consumers of electricity in the town, and applications have been made for motors for trade purposes. The work of laying down cables up Park-place and Dumfries-place is being pushed forward as rapidly as possible, and it is anticipated that there will be a good many consumers in and between these two streets, where there is some good residential property Several of the occupiers have already wired their houses in readiness for the introduction of the new illuminant. Other extensions will be up Cathedral-road, the cables being conveyed from Tudor-road through Clare-street and Newport-road as far as Oakfield-street. These new works are for the benefit of private consumers only, and there is no intention at present of lighting the streets named with electricity.

Ulverston.—A report has been presented to the District Council by the Electric Lighting Committee, and, in moving the adoption of this, Councillor Hodgson said the committee, along with the representatives of the Local Boards of Grange and the Ulverston Rural Sanitary Authority, had had several interviews with the solicitors of the Windermere and District Electric Supply Company, who were applying to the Board of Trade for a provisional order, and he hoped and trusted they had come to some satisfactory terms with the company. Of course, while the negotiations were in progress, these terms could not fairly with advantage to either side be made public, but he might say they were perhaps quite as fair as they could possibly get. The motion was agreed to after some discussion.

Bath.—The Lighting Committee of the Bath Corporation invited Mr. F. H. Medhurst, B.Sc., M.I.E E., to confer with them last Monday, and to advise them with regard to their proper procedure in opposing the application of the Bath Electric Lighting Company for a provisional order. The Urban Sanitary Authority had already passed a resolution refusing its consent to the application of the company, but Mr. Medhurst was of the opinion that a purely negative policy would not be likely to avail with the Board of Trade, and he cited the decisions of the Board of Trade with regard to Newmarket and Bedford in support of his views. Finally, Mr. Medhurst's advice was adopted, and a resolution carried that his worship the Mayor be requested to call a special meeting of the Urban Sanitary Authority for Friday (to-day) in order to consider, and if thought fit to pass, a resolution that the Authority itself apply for an electric lighting provisional order at the earliest possible date.

Manchester.—A meeting has been held of the City Council, at which Mr. Alderman Gibson, in submitting the minutes of the Gas Committee, called attention to the suggestion of the Electric Light Sub-Committee that the town clerk, in consultation with a special sub-committee should take the requisite steps for increasing the borrowing powers of the Corporation for electric supply purposes to such an amount as may be found necessary to supply the increased demand for electric current. The amount that it was expected would be required was £100,000. The Council would remember that they first put down a plant for the supply of 20 000 16-c.p. lamps. It was thought that would last for two or three years. That, however, was soon taken up, and provision had since been made for a further 8,000 16-c.p. lamps, and the committee had to-day customers for 27,000 16-c.p. lamps, and the cry was "still they come." The proceedings were approved, and so also was a special resolution directing that the necessary steps be taken for borrowing £100,000.

Notting Hill.—The newly-elected Vestry of Kensington had under consideration last week a letter from Messrs. Romer and Haslam, solicitors for the Notting Hill Electric Lighting Company, Limited, pointing out with reference to the report of the Select Electric Lighting Committee which was before the Vestry on December 5, dealing with their application for the consent of the Vestry to the grant of a provisional order for an extension of the company's area in North Kensington, that the present rule of the Board of Trade dispenses with the requirement of the Act as regards the one month's notice referred to in the committee's report, and urging that the consent of the Vestry should be given to the grant of the order at their next meeting, as the company had to be in a position to prove such consent on the 15th inst. The Vestry consented to the granting by the Board of Trade of a provisional order to the company for the supply of electricity in that portion of the parish of St. Mary Abbott's, Kensington, situated north of the area comprised within the company's principal order of 1889, subject to the right being reserved to the Vestry to object to the granting of the said order should any variation to which the Vestry may take exception be made in the draft now approved by them.

Birkenhead.—In the minutes of the Finance Committee of the Town Council it was resolved that Mr. Shoolbred be requested to prepare and submit to the committee the complete working plans, etc., in connection with the erection of the central electrical generating station, and the establishment of the necessary works in regard to the installation in order that quantities might be taken out and tenders obtained. Alderman Rawcliffe said he hoped the Finance Committee would approve of his suggestion that the work be placed in the hands of a special committee, for a very large sum of money was about to be spent, and a large amount of detail gone into. While they were all very grateful to the Finance Committee for the excellent way they had attended to these matters, it would be far better to relieve the committee from any detailed work, and from the handling of so great an expenditure. Alderman Deakin assured Alderman Rawcliffe that he was of the same opinion, and the committee would also agree that they were not the body to be entrusted with the control of the working of the scheme. Whether it went under the control of the Gas and Water Committee, or a special committee, would be determined afterwards. The Mayor suggested the desirability of a meeting being arranged between the Gas and Water and Finance Committees—the committees from whom would probably be chosen the body for the purpose of having the scheme in hand. Alderman Rawcliffe said, as the Finance Committee was itself composed of the chairmen of the other committees, their undertaking the selection of such a committee would no doubt be agreed to by the Council. The subject closed with this understanding.

Steamship-Lighting.—The *Indian Engineer* states that some interesting experiments have lately been carried out on the R. S. Company's steamship "Scinde" with regard to the possi-

Digitized by Google

bility of night running in the Sunderbunds by the aid of the electric search-light A large party of guests assembled on board to witness the trial-run of the plant, which consisted of a 25,000-c.p. projector worked by a vertical engine (Marshall's), and dynamo placed on the upper deck—off Koila Ghat. The search-light was shown on different vessels down the river with the long-distance lens on, and then put on the bank with the diverging lens which throws the light in a wide flat beam, the trial proving in every way satisfactory, and she left the next morning, making a most successful run to Naraingunge and back in 12 days. Although detained frequently at night on account of tides and fog, Captain Ainsley reported most favourably on the light as an aid to navigation at night; and as the "Scinde" has just made a second trip to Naraingunge in even shorter time with the light, under the command of Captain Elder, there is no doubt that in the near future we shall see most of the boats running through the Sunderbunds both by night and day, which will be a great advantage to the tea and jute traders. While lying at the jetties at Naraingunge the "Scinde" illuminated them to facilitate night working by large incandescent lamps hung over her sides in reflectors. The whole plant was supplied and erected by the Oriental Telephone and Electric Company, and Mr. Lester Betts, the manager of their Calcutta branch, who has had a large experience of search-light work on the China rivers, accompanied the steamer on her first trip.

Liverpool.—A new building has been erected by the Corporation at the corner of Roe-street. The basement will be used for the storing of fittings in connection with street lamps and as a workshop for lamp repairing. The ground floor has been utilised as an office for both the gas and the electric light department, while the upper floor is devoted entirely to the testing of gas-meters. The Liverpool City Council, on Wednesday, adopted, by 29 votes to 13, a recommendation of the Special Lighting Committee that the Council should offer to purchase from the Liverpool Electric Supply Company, Limited, the whole undertaking of the company as a going concern this year, instead of waiting until the period when the Corporation could compel the company to sell, at price, terms, and conditions, as may be agreed upon between the company and the committee, and failing such agreement, as may be settled by arbitration. The committee were authorised to take the necessary steps to carry out the objects of the resolution. Alderman Forwood said if arbitration were resorted to he would not be surprised if the company preferred a claim for £500,000, and he deprecated giving the committee what might be called a blank cheque. At the same meeting the Town Council authorised the Special Lighting Committee to take steps to ascertain the cost of a scheme for supplying all the public buildings and markets in the city with electric light from a generating station or stations to be established by the Corporation. The buildings proposed to be lighted are all within a radius of half a mile, and at the present time the Council have to pay in respect to those buildings nearly £4,000 a year for gas. The committee are to obtain estimates from the Liverpool Electric Supply Company, Limited.

The Copper Markets.—Messrs. Steadman, Crowther, and Co., in their annual metal report for 1894, say in regard to copper that the production was curtailed, presumably under the stress of low prices, and will be further reduced if the arrangement between the big American and European producers can be again brought into force. There seems more disposition to send refined copper only to this country, and the largest American mines will send their European supplies in this form in the future. Exports fell off very considerably in refined sorts to the Continent, and in copper sheets to India, but an equal quantity of yellow metal was taken. Although copper sheets were very cheap, being offered in July at £46 5s, yet the advantage to Indian buyers was nullified by the lowness in exchange. The heavy Birmingham trades were fairly active, especially in tubes. Competition was very severe, and the unfavourable balance-sheets of some of the large companies show the difficulty of finding profitable employment. Foreign makers offered copper wire cheaper than it could be produced in this country, but English-made brass wire still held its own. A renewal of heavy shipments from the States early in the year prevented any confidence being felt in the future of the metal. Notwithstanding that deliveries were good and stocks in the aggregate diminishing, copper did not respond to the statistical improvement. In the open market warrants were sold at £42. 17s. 6d. in January, and this proved to be the highest value throughout 1894. There was an almost continuous fall throughout the first half of the year. By June it had dropped to £37. 17s. 6d., the lowest recorded price excepting during the time following the collapse of the copper syndicate in March, 1889. Some improvement followed, but £38 was again accepted in July. The market then turned round on rumours of proposals for a renewal of the agreement for the restriction of output, and 50s. per ton was soon gained. There was a gradual improvement throughout August and September, until £41. 15s. was reached. In October and November some realisations took place, doubtless influenced by the disappointment following the passing of the American Tariff Bill, and little by little the market drooped until £39. 15s. was touched early in December, when then was a rebound to £41, and this was the value on the last day of the year.

Wednesbury.—A report of the General Purposes Committee, brought up at a recent meeting of the Town Council, contained a paragraph relating to the cessation recently, for a time, of the electric tramcar traffic between Wednesbury and Walsall, and stating that the town clerk called upon the company to carry out their statutory obligations, and informed them that the Corporation would not consent to a resumption of traffic by steam power. Alderman R. Williams urged that the Corporation ought to do all in their power to induce the tramway company to adopt electric trams for all parts of their system. He trusted that the Corporation would not lose sight of their power in this matter, and he believed the company would not object to a little pressure on the subject. Mr. Oldbury reminded the Council that the extended period over which the company were empowered to use steam would expire on the 15th inst. The temporary stoppage of the electric trams caused great inconvenience, and there would be still greater inconvenience if the steam trams were stopped, as probably they would be unless the Town Councils of Wednesbury and West Bromwich went to the Board of Trade and asked for a further extension of time. West Bromwich was thoroughly opposed to the electric system because of the pillars which were required, or that system would probably have been applied long since to all parts of the company's lines; and, looking forward to the time when they could take possession of the line from Handsworth to West Bromwich, were asking for an extension of the cable system to the latter place. But if such an extension were brought about, Wednesbury would suffer still greater inconvenience and loss, because numbers of people who at present visited the town on market days would find difficulties put in their way. He suggested that the town clerk should attend a Board of Trade enquiry as to the causes of the recent explosion, and express the views of the Council. The Mayor proposed a resolution to that effect, and spoke in favour of the electrical system as the best, at the same time expressing an opinion that the cable system, which the West Bromwich Corporation desired the Corporation to adopt, would be too costly for them to undertake. The pillars might be unsightly, but people got accustomed to them, and the annoyance was not so great as that caused by the constant rumbling of the wire on the cable system. Mr. Pritchard seconded the proposition, which was agreed to.

Collier Audible Telephone Syndicate, Limited.—From the observations of the official receiver and liquidator (Mr. S. Wheeler) issued under a winding-up order made in this case on July 19 last, it appears that the syndicate was registered on April 16, 1891, and was formed to purchase and further develop patent rights granted to Mr. Arthur Thomas Collier for an improved audible telephone; to take out foreign patents for the same; to acquire the new machinery and plant at the works, 38, Gray's-inn-road; and generally to carry on the business of a telephone and electrical manufacturing and supply company. The nominal capital of the syndicate was £9,000, divided into 90 ordinary shares of £100 each. The London and Colonial Finance Corporation, Limited, now in voluntary liquidation were the promoters of the syndicate The official receiver, after giving some further details, states that, immediately after allotment, the syndicate commenced operations, which appear, however, to have consisted almost exclusively of experimental works in connection with the vendor's inventions. These experiments very quickly absorbed the working capital, and it was found necessary almost at the outset to obtain financial assistance from the corporation in the shape of a loan for £300, which was subsequently increased to £750 Early in 1892 the directors appear to have had under consideration a scheme for the formation of a new company to take over the assets of the syndicate, and on August 10, 1892, the new company was registered under the title of the Collier-Marr Telephone and Electrical Manufacturing Company, Limited, and, under an agreement dated December 31 following, took over the whole of the assets of the syndicate as a going concern, the consideration being £50,000, payable as to £46,000 in shares and £4,000 in cash. For the purpose of carrying out the sale of the assets to the new company, the syndicate went into voluntary liquidation on October 17, 1892, and a liquidator was appointed. The statement of affairs of the syndicate, submitted by the voluntary liquidator, shows liabilities £645, of which £606 are unsecured, there being an estimated surplus after meeting the liabilities of the syndicate, subject to cost of liquidation, of £25,617. The official receiver, after giving some further information, observes that there are matters in connection with the conduct of the business of the syndicate, and of the voluntary liquidation, which require further investigation.

Leeds Tramways—A meeting of the Town Council has been held, at which, when the minutes of the Highways Committee came up for confirmation. Mr. Denton Houghton rose and said he was not going to complain of the amount that had been spent by the eight gentlemen who formed the Tramways Committee, and who had up to the present time spent £207, or £26 per member, in visiting various places on the subject of tramway traction, the recent expedition to Paris by Alderman Firth and the city engineer having cost 50 guineas. The tramways had been in the hands of the Corporation 11 months; the committee had been gallivanting all that time, and it was time the Council had a report from them. He fancied the committee had forgotten what they had seen on their visits. Mr. Battle suggested that each member of the deputations should submit his own report. If the report was to emanate from the city engineer alone, they might as well have sent him alone. He hoped they would not have a report of one system only. Alderman Firth, chairman of the Highways Committee, replied that the report, when it was printed, would not be the report of the city engineer. Each member would, of course, be at liberty to express his own individual opinion as to what he believed was the best system of haulage. The Council could not make a greater mistake than to press for the committee's report. The Council had everything to gain by delay and nothing whatever to lose. As an instance he might mention that one system of haulage had developed during the last six months more than it had developed in six years before.

Digitized by Google

The minutes of the committee were adopted. In order that the provisions of the Borough Funds Act might be complied with, a meeting of property-owners and ratepayers was held on Tuesday in the Council-chamber at the Town Hall to consider the Corporation Tramways Bill, which is to be promoted during the coming session of Parliament. The Mayor (Alderman Gilston) was in the chair, and amongst those present were about a dozen members of the Council, some Corporation officials, and a few of the general public. The proceedings, which were purely formal, began with the reading of the notice summoning the meeting by the town clerk, who also briefly enumerated the provisions of the Bill, especially that empowering the Corporation to work the tramways. The Mayor proposed, "That this meeting of owners of property and ratepayers of the city of Leeds do consent to the promotion by the Council of the city in the next session of Parliament of the Bill now produced to the meeting, and intituled 'A Bill to empower the Mayor, aldermen, and citizens of the city of Leeds to construct additional tramways, and for other purposes.'" Alderman Firth, without comment, seconded the motion, which was agreed to *nem. con.* The meeting then terminated.

PROVISIONAL PATENTS, 1895.

JANUARY 1.

30. **Improvements in gear-wheels for electromotors and applicable to other purposes.** James Cardwell Quinn and Robert McDougall, Globe Works, Holland-street, Pendleton, Lancs.

42. **Improvements in and connected with telephonic apparatus as adapted to mining and other purposes.** Max Binswanger, 73, St. Stephen's-road, Upton Park, London.

52. **Improvements in electric lighting apparatus for railway cars.** William Biddle, 33, Chancery-lane, London.

56. **Improved electrical cut-out.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.) (Complete specification.)

57. **A method of ascertaining the difference of electric potential at a distant extremity of conductors.** John Hopkinson, 28, Southampton-buildings, Chancery-lane, London.

60. **An improvement in electric arc lamps.** Walter Stevens, 1, Old Serjeant's-inn, Chancery-lane, London.

65. **Improvements in dynamo brushes.** The London Electric Wire Company, Limited, and John Willey, Anchor Works, Playhouse-yard, Golden-lane, London.

82. **Improvements in and relating to electric winding mechanism for clocks.** Carolus Arnold, 45, Southampton-buildings, Chancery-lane, London.

JANUARY 2.

106. **Improvements in primary batteries.** Edward Moses Levetus, Hymen Levetus, and Walter Rowbotham, 47, Vittoria-street, Birmingham.

107. **Improvements in primary batteries.** Edward Moses Levetus, Hymen Levetus, and Walter Rowbotham, 47, Vittoria-street, Birmingham.

148. **Improved methods and apparatus for measuring electrical currents.** Oliver Blackburn Shallenberger, 28, Southampton-buildings, Chancery-lane, London.

157. **Improvements relating to telephone call stations with automatic charge or fee-receiving devices.** Christian Albert Jensen, 77, Chancery-lane, London. (Nicolai Jacobsen, Norway.) (Complete specification.)

JANUARY 3.

176. **Improvements in connection with arc lamps more particularly adapted for electric search-lights.** Frank Michael Lewis, 2, East-parade, Leeds.

178. **Improvements in the manufacture of shades and shade frames for oil, gas electric, and other lamps.** Henry Brittain and Samuel Henry Brittain, 263, Balsall Heath-road, Birmingham.

185. **Improvements in telephonic apparatus for simultaneous telegraphy and telephony on the same line wire.** George Henry Bassano, 23, Lodge-lane, Derby.

226. **Improvements in electric call and alarm apparatus.** Ernst Herz and Jean Pierre Hartfuss, 18, Buckingham-street, Strand, London.

JANUARY 4.

230. **An improved automatic cut-out for electric circuits.** William Kingsland, 139, Upper Mostyn-street, Llandudno.

231. **Improvements in primary batteries.** Edward Moses Levetus, Hymen Levetus, and Walter Rowbotham, 47, Vittoria-street, Birmingham.

238. **Improvements in fittings for electric lamps.** Archibald Denny and Alexander Campbell Cormack, 87, St. Vincent-street, Glasgow.

261. **An improved electric stamper battery for ore crushing.** Francis Hodge, 18, Fulham-place, Paddington, London. (Charles Evensen, New Zealand.)

281. **Improvements in and connected with telephones.** Hermann Oppenheimer, 55, Redcross-street, London.

285. **Improvements in holders for electric incandescent lamps.** Theophilus Coad, 37, Cursitor-street, Chancery-lane, London.

297. **Improvements in the electrolytic treatment of tin and its separation from alloys and mechanical mixtures.** Carl Frederick Claus, jun., and Herbert Selwood Sutton, 151, Strand, London.

298. **Improved means for supplying an electrical current and safety devices for use in combination therewith with electric tram and other cars or vehicles.** Jean Claret and Olivier Vuilleumier, 47, Lincoln's-inn-fields, London.

JANUARY 5.

348. **Improvements in rectifiers for electrical currents.** William Burrowes Close, 4, South-street, Finsbury, London. (Complete specification.)

351. **Improvements in electric arc lamps.** James Eglington Anderson Gwynne and Rankin Kennedy, 11, Furnival-street, Holborn, London.

357. **An improved street, road, or underground junction-box for electric conductors.** James Thomas Rossiter, 46, Lincoln's-inn fields, London.

358. **Improvements in electrodes for secondary batteries.** J. Wershoven, 46, Lincoln's-inn-fields, London.

SPECIFICATIONS PUBLISHED.

1893.

15906. **Electrolytic apparatus.** Young. (Société Outhenin Chalandre Fils et Cie) (Second edition.)

23833. **Switches or relays for alternating currents, etc.** Aron.

24951. **Electrical measuring instruments.** Nalder and others.

1894.

496. **Heating or welding metals electrically.** Thompson. (Coffin.)

835. **Electrolytic apparatus, etc.** Hargreaves and Bird.

3101. **Dynamo-electric machines.** Sayers and others.

3291. **Electric arc lamps.** Money and Nash.

3863. **Electric arc lamp.** Jones.

21707. **Electric conductors of electric railways.** Slater. (Platt.)

NOTES.

New Book.—Messrs. Longmans, Green, and Co. will shortly publish a work on telephony by Mr. A. R. Bennett.

Gustave Trouve.—A short sketch of the work accomplished by M. Gustave Trouvé is given in *L'Athénés*, a new Paris journal published at 6, Rue des Ecuries-d'Artois.

Award.—The commission of the mechanical section of the French Academy of Sciences have awarded a prize of 2,000f. (£80) to Mr. Leblond for his work in connection with electricity.

Trade Review.—A trade review of the business done by electrical firms during 1894 is being published in a German contemporary. This seems a new departure for our friends in that country.

Danger of Coal Gas.—The danger of using coal gas as an illuminant has once more been exemplified, seven persons having been suffocated a few days ago by inhaling this kind of gas at Springburn, Glasgow.

Electric Lighting in Rangoon.—A meeting of the Public Works Sub-Committee of the Rangoon Municipality has been held, when it was resolved to recommend the General Committee to call for tenders for lighting the town by electricity.

Institution of Electrical Engineers.—A meeting of the Institution will be held on Thursday, 24th inst., when a paper will be read on "The Origin and Development of the Telephone Switchboard," by Mr. J. E. Kingsbury, associate.

Royal Society.—Papers on the following subjects were down for presentation yesterday (Thursday) afternoon: "The Latent Heat of Evaporation," by Mr. E. H. Griffiths; and "On Slow Changes in the Magnetic Permeability of Iron," by Mr. W. M. Mordey.

Society of Arts.—The second Cantor lecture on "The Arc Light," by Prof. Silvanus P. Thompson, D.Sc., F.R.S., will be delivered on Monday. It will deal with the optics of the arc, the temperature of crater and of peak, and the distribution of light and of invisible radiation.

Personal.—Lord Kelvin has accepted an invitation to be present at the annual dinner of the Wolverhampton Chamber of Commerce on the 30th inst.—Mr. W. J. Hope-Johnstone, who was clerk of works during the equipment of the Bedford station, has now been appointed electrical engineer.

Books Received.—We have received from Messrs. Whittaker and Co. "Steelworks Analysis," by Mr. J. O. Arnold, F.C.S. This forms one of "The Specialists' Series."—A copy of a new and revised edition of "Electrical Engineering," by Messrs. W. Slingo and A. Brooker, has reached us from Messrs. Longmans, Green, and Co.

Section Lining Code.—A useful code of section lining has been issued, at the price of 1s., by Mr. James P. Maginnis, A.M.I.C.E., M.I.M.E. The code is to serve as a guide to young draughtsmen and others, for indicating on drawings and tracings the various materials generally used in engineering construction where it is impossible to indicate the materials by the usual colours. A code of this kind should be fixed up in every drawing office.

The Pacific Cable.—A Reuter's cablegram from San Francisco, dated 13th inst., states that Mr. Hatch, Hawaiian Minister for Foreign Affairs, arrived there that day from Honolulu, on his way to Washington. His object is to push forward the project for laying a telegraph cable from San Francisco to Honolulu. He declares that the Hawaiians dislike the idea of having foreign capital in the enterprise, and will only accept it as a last resort.

Manchester Literary and Philosophical Society. We have received a copy of the *Proceedings* of this society, containing a memoir by Mr. Henry Wilde, F.R.S., "On a Magnetometer for showing the Influence of Temperature on the Magnetisation of Iron and other Magnetic Substances." The *Proceedings* are issued from 36, George-street, Manchester.

Northern Society of Electrical Engineers.—The following new members and associates were elected at the meeting on Monday. Members: J. G. Calvert, Manchester; S. H. Casson, Manchester; M. Holroyd Smith, London; A. Stahl, Manchester; P. C. Pope, Burnley; A. H. Robinson, Liverpool; Wm. Lawrie, Prescot; G. B. Samuelson, London; F. C. Gibbons, Manchester. Associates: S. Hartford, R. Wood, and A. L. Lind—all of Manchester.

Institution of Mechanical Engineers. — The forty-eighth annual general meeting of this institution will be held at 25, Great George-street, Westminster, on Thursday evening, 31st inst., and Friday evening, February 1, when the following papers will be read: "The Determination of the Dryness of Steam," by Prof. W. Cawthorne Unwin, F.R.S.; and "Governing by Throttling and by Variable Expansion," by Captain H. Riall Sankey.

Cleaning of Commutators.—A new preparation, termed "Commudine," has been brought out as a preservative for the commutators of dynamos and the collectors of alternators. The London Electrical Goods Agency, of 53, Victoria-street, S.W., who have sent us a bottle of the preparation, state that it is the only article produced for the purpose, that it removes greasy oxide with the greatest facility, that it does not foul the brushes or damage the insulation between the commutator segments, and that it allows the commutator to develop a hard surface not liable to abrasion.

Municipalisation of Tramways.—The London County Council received on Tuesday the report of the Highways Committee, stating that the Board of Trade had signified their approval to the service of a notice upon the London Tramways Company requiring the company to sell to the Council the whole of the tramways, works, and undertaking authorised by the Metropolitan Street Tramways (Extension, etc.) Order, 1873, and the Pimlico, Peckham, and Greenwich Street Tramways (Extensions) Order, 1873, as confirmed by the Metropolitan Tramways Confirmation Acts, 1873.

Liverpool Engineering Society.—At the fortnightly meeting of this society held on Wednesday evening, the 9th inst., at the Royal Institution, the president, Prof. H. S. Hele-Shaw, M.I.C.E., in the chair, a paper was read by Mr. John A. Brodie, Wh.Sc., A.M.I.C.E., entitled "Tramways and Tramway Traction." The author, after a general *résumé* on tramways, dealt in detail with the question of permanent way, and then proceeded to discuss the relative merits of horse, locomotive, cable, and electric traction, and the comparative costs of these systems. A discussion upon the paper terminated the proceedings.

Transformer-Chambers.—The Board of Trade has addressed communications to the London County Council, the Wandsworth District Local Board of Works, and other local bodies which recently raised objections to the proposals of electric lighting companies to place transformer-chambers below the surface of the public thoroughfares. The letters, we are glad to say, are to the effect that the Board has adopted the advice given by Sir Courtenay Boyle, that, if proper precautions be adopted to secure the public safety, the Department would not be justified in forbidding the use of transformer-chambers in the way suggested.

Digitized by Google

Sir Courtenay Boyle's remarks on the subject will be found in our issue of December 21, 1894.

Germany's Four Principles.—In the course of a review of technical development in the applications of electricity during 1894, the *Elektrotechnische Zeitschrift* states that the use of accumulators in central stations in Germany has greatly progressed. On the other hand, alternating-current stations have also been extended; and the four principles—moderate periodicity, large units, slower speed, and direct coupling—have fairly throughout been introduced in German works. Our contemporary submits that the rotary-current system bids fair to be adopted in new stations in preference to the ordinary alternating system.

Telephone Concert in Hungary.—The *Standard's* Vienna correspondent says that on Saturday last "an extraordinary concert and ball took place last night in the Hungarian town of Temesvar. The audience listened, by means of audible telephones distributed around the ball-room, to a military orchestra playing at the town of Arad, to duets and songs in Szegedin, to a chorus sung by a glee club at Szabadka, and to popular songs by celebrated artists in three different theatres at Budapest. The quartette at Arad was as distinctly heard as the 'Rakoczy March' that was telephoned from Szegedin. Finally, the young people present danced for hours to the music alternately played in all three towns and in Temesvar itself, outside the ballroom. It is believed that no such concert has ever taken place before in Europe."

Royal Meteorological Society. — The annual meeting of this society was held on Wednesday evening, the 16th inst., at the Institution of Civil Engineers, Great George-street, S.W.; Mr. R. Inwards, F.R.A.S., president, in the chair. The council, in their report, reviewed the work done by the society during the past year, and also stated that additional accommodation had been provided to meet the growing needs of the library. Forty-five new Fellows had been elected during the year. Mr. Inwards, in his presidential address, dealt with the subject of "Weather Fallacies," which he treated under the heads of saints' day fallacies, sun and moon fallacies, and those concerning animals and plants. He also referred to the almanac makers, weather prophets, and impostors who have from time to time furnished the world with fit materials for its credence or its ridicule. Mr. C. Harding then read a paper on "The Gale of December 21 and 22, 1894, over the British Isles."

Advantages of the American Patent System.—The *Scientific American* states that Mr. Edison has lately obtained several patents which have for years been pending in the Patent Office. One is for the manufacture of carbons, filed in 1880, fourteen years age. Another for dynamo regulator, filed in 1881, thirteen years ago. A third for plating metals, filed in 1884, ten years age. A fourth for carbon filaments, a fifth for electric distribution, both filed in 1886, eight years ago. In 1892 Mr. Edison also received four patents for telephones, the applications for which were filed in 1877, fifteen years before the issue of the patents. Continuing, our contemporary says: "It is evident there is something wrong in the law which thus facilitates and apparently encourages these unconscionable delays. Preliminary litigations, it appears, may be carried on for half a generation before the Patent Office prior to the grant of a patent. And, then, after the issue of the patent, battles in the courts are begun to settle the validity of the grant."

Electrolysis of Copper Sulphate.—An abstract is given in the *Journal* of the Chemical Society of a communication made by Mr. A. Chassy to the *Comptes Rendus* on this subject. The author states that when a hot solution of copper sulphate is electrolysed a remarkable violet-red deposit is usually obtained. With platinum electrodes and a current of 00·1 ampere per square centimetre an almost neutral saturated solution of pure copper sulphate at 100deg. yields a bright-red deposit of microscopic crystals derived from the cube and octahedron. These crystals consist of cuprous oxide. Below 100deg. the cuprous oxide becomes mixed with crystals of copper, the proportion of which is higher the lower the temperature. A similar effect is produced by increasing the strength of the current or diluting the solution. If the positive electrode consists of copper, its loss of weight is always distinctly lower than the gain in weight of the negative electrode. Moreover, if the voltameter containing the hot solution is connected in the same series with a voltameter containing a cold solution, the weight of the deposit in the former is always much greater than would correspond with the oxidation of the copper deposited in the latter.

Electric Lighting in Germany.—The Dortmund Municipality have had under their consideration the question of erecting a central electric light station. A favourable offer was received from the Allgemeine Elektricitäts-Gesellschaft, but the authorities have decided to establish a station on their own account.—Messrs. Kramer and Co., of Berlin, propose to establish a central station in the Upper Silesian iron-smelting district, intending not only to supply current therefrom for lighting and power purposes to various places in the district, but also to work several electric tramway lines.—A central electric light station is to be established at Hechingen.—Plans are being prepared for a central station at Warnsdorf which will not only supply current to the whole of the town, but also to the neighbouring villages of Niedergrund and Obergrund and the town of St. Georgenthal. The station will also be used in connection with a new electric tramway.—At Heilbronn, the electric light station, which is operated by turbines, has had to shut down owing to the amount of ice in the Neckar.—Messrs. Teumer and Kreyfeldt, who propose to establish a central station at Hirschberg, have issued circulars in order to ascertain the probable demand for current.

The Walker-Wilkins Battery.—In another part of the present issue will be found a report on this battery, which is being introduced by the Patent Non-Polarising Voltaic Battery Company, of Spring Hill Wharf, Birmingham. In the course of a letter to us the company state: "The novelty of the cell is that it depends upon the atmosphere as its depolarising agent instead of costly chemicals. By the action of the battery, nascent hydrogen occurs on the surface of the carbon constituting the negative element, and meeting with the condensed air in the pores of the carbon, combines with the oxygen of the same, the supply of air passing through the perforations. The hydrogen thus never assumes a gaseous form, and polarisation is prevented. The life of the electrolyte is remarkable, as will be seen from Prof. Jamieson's report. Its cost is very low—viz., 8d. per gallon—and in the three-cell oval type the quantity of solution is under three quarts, and its cost is therefore 6d. — giving 768 ampere-hours. Sufficient height of porous cell is allowed for feeding purposes; cells require feeding once per week. The oxide is recovered from the exhausted solution with the greatest ease, solution resuscitated and used again from time to time with a percentage of loss in treatment."

Dynamos and Coupled Plants.—A well illustrated machine catalogue, dealing with dynamos, motors, and direct-coupled plants, has been issued by Messrs. Laing, Wharton, and Down, of 82A, New Bond-street, W. One

Digitized by Google

of the most noticeable features of the illustrations is the application of electric power. Thus, for instance, the frontispiece shows a factory, or the machinery and tools contained in it, driven by a large "L. W. D." type of motor. Then, again, a view is given of a 100-h.p. dynamo installed for the transmission of power, and another illustration showing the motor to which the current is conveyed. In the list of dynamos two tables are given showing the relation of speed to output, which apply equally to the capacity of the motors at various speeds. One of the main features of these generators is the provision of an alternative winding, by means of which and the changing of a switch a compound machine can be used for charging accumulators. Various types of dynamos, including arc, incandescent, and plating and depositing machines, are shown—one generator being coupled direct to a turbine and another to a vertical engine. The coupled plants are specially intended for shiplighting, factories, and central stations, where room is a consideration.

Electric Heating of a Theatre.—The lessees of the Vaudeville Theatre found it necessary during the recent severe weather to provide some system of warming the theatre. Mr. Henderson, the manager, after having considered several systems of heating by hot water, steam, etc., decided to adopt electric heating on account of the many advantages of the system. Messrs. Crompton and Co., of Brompton-road, were thereupon called on to supply at once electric heating apparatus suitable for carrying out the work. The order was received at 11 o'clock on Tuesday morning, and by six in the evening the theatre was being warmed electrically. Although no mention had been made in the theatre of any system of heating having been adopted, many persons remarked on the increased warmth and comfort. The large radiators used were perfectly portable, and, owing to this fact, it was found possible to place them in the stalls during the day, and remove them to the sides of the theatre in the evening. We are glad to learn that Messrs. Crompton and Co. have now received the order for the permanent warming of the theatre, and in a short time it is expected the new system will be completed. The cost is not expected to exceed that of other systems, and this, combined with the advantage of freedom from danger, with perfect regulation, should make electric heating very popular for the warming of theatres.

Electric Traction in Germany.—The project for an electric railway between Stralau and Treptow Park, Berlin, passing by a tunnel under the Spree, has been approved by the authorities concerned.—An electric tramway is projected between Elberfeld, Hahnerberg, and Hasten.—At Dresden the local authorities have sanctioned the adoption of electric traction on the four lines of the Dresden Street Tramway Company and of the German Street Tramway Company. The new system will come into operation in October. Current will be obtained from the municipal central electric light station.—The electric tramway through Marienthal, with a branch to the Wartburg, to which we have already referred, is to be carried out jointly by Messrs. Bachstein, railway engineers, and the Allgemeine Elektricitäts-Gesellschaft, of Berlin.—Authority has been given for the construction of a suspended railway on the Langen system at Hamburg. Both banks of the Elbe will be connected by it by means of a high-level bridge.—An electric tramway has been opened this month at Hagen, Westphalia, copper-zinc accumulators being employed. This is the first line of the kind in Germany. The work has been carried out by the Hagen Accumulator Works. Four cars are in use. They are of the ordinary size, carrying 26 passengers. Under each of the two seats there is a wooden battery trough carrying 44 copper zinc cells, or 88 in all. The motor is of 15 h.p.

Electrical Conductivity of Organic Salts.—Mr. A. Bartoli, in the *Gazzetta*, deals with the dependency of the electrical conductivity of organic salts on the temperature. The paper describes the result of a continuation of the author's investigations of the electrical conductivity of organic substances; he draws the following conclusions from a study of about 60 aliphatic salts. At ordinary temperatures, or at the boiling points, the electrical conductivities of aliphatic alkylic salts of small molecular weight are greater than those of their higher homologues. The electrical conductivity of such salts increases with the temperature, the coefficient of increase of conductivity being greater for salts of high molecular weight than for their lower homologues; the temperature coefficient of the conductivity therefore increases as the viscosity of the salt increases. In the one or two cases in which the conductivity decreases with rise of temperature, the anomalous behaviour can be explained by assuming the presence of a trace of an aliphatic alcohol. The conductivity of a salt may be caused to decrease with rise of temperature by adding from 1 to 20 per cent. of any aliphatic alcohol; the electrical conductivity of a salt still increases as the temperature is raised on adding to it aniline, paraldehyde, a phenol, a ketone, or an acid.

Electro-Harmonic Society.—A smoking concert will be held on Friday, January 25, 1895, at the St. James's Hall Restaurant (Banquet-room), Regent-street, W., at eight o'clock. The artistes will be the Dilettante Vocal Quartette, Mr. James Brown, Mr. Frederick Bevan, Mr. Edward Dalzell, and Mr. Robert Hilton; solo bassoon, Mr. E. F. James; solo pianist, Mr. Alfred E. Izard. Musical sketches will be given by Mr. George Pritchard. The musical directors are Messrs. T. E. Gatehouse and Alfred E. Izard. Programme—Part I.: glee, "Sigh no More, Ladies" (R. J. S. Stevens), the Dilettante Vocal Quartette; new song, "The Mighty River" (F. Bevan), Mr. Frederick Bevan; pianoforte solo, "Caprice" (Schumann), Mr. Alfred E. Izard; aria, "Where'er You Walk" (Handel), Mr. Edward Dalzell; musical sketch, Mr. George Pritchard; song, "Still is the Night" (Franz Abt), Mr. Robert Hilton; bassoon solo, "Variations and Rondo" (Kalliwoda), Mr. E. F. James; humorous part song, "Simple Simon" (specially arranged), the Dilettante Vocal Quartette. Part II.: part song, "Thinking of Home" (Millard), the Dilettante Vocal Quartette; new song, "The Old Soldier" (F. Bevan), Mr. Frederick Bevan; bassoon solo, "The Lowly Youth" (J. H. Young), Mr. E. F. James; song, "An Evening Song" (Blumenthal), Mr. Edward Dalzell; musical sketch, Mr. George Pritchard; song, "My Lodging is the Cellar" (D'Alquen), Mr. Robert Hilton; glee, "Amo, Amas" (Shield), the Dilettante Vocal Quartette.

Electric Traction in France.—It is proposed to extend the Bordeaux-Bouscat-Vigean electric tramway to the Quay Louis XVIII.—The electric tramway at Dijon will shortly be opened for public traffic. Trials which have been made have proved very successful.—An interview has taken place between the mayor of Lille and the management of the new tramway company, at which the former represented inhabitants who objected to posts carrying the trolley wires being placed opposite their houses. It was explained that agents of the company had been instructed to obtain permission from house owners for wall brackets to be fixed, and poles had only been erected where such permission had not been obtained. It is expected that the line will be opened by the end of the month. It would appear

Digitized by Google

from a report published in a local paper that very friendly rivalry exists between French promoters of systems of electric traction for Toulon. No less than 12 companies sent in to the tramway company schemes for converting their lines from horse haulage to electric traction, and the company have now decided in favour of the trolley system. It is intended to place on the lines 30 cars, each equipped with two motors of 15 h.p.—It is intended to construct three lines of electric tramways at Le Mans, the first from the railway station to the end of the Rue des Maillets, the second from the hospital to the octroi depot on the Paris road, and the third from the Place de la Croix d'Or to the Place de la Lune. The Municipality will apply to the State for the necessary concessions, and then pass them over to Mr. E. Faye, who has the concession for the Dijon electric tramway.—Mr. Roy is promoting a scheme for an electric tramway to connect the old town of Lourdes with the newer quarters.

Municipal Electricity Works.—Some discussion having taken place in German papers and at meetings of some town councils as to the commercial position of municipal electricity works, Mr. Max Meyer, of Nurnberg, thinks it advisable to give some information on the subject. He has accordingly availed himself of the columns of the *Elektrotechnische Zeitschrift* of the 10th inst. for discussing the matter. The author states from the official reports published of the working of German stations that the anticipated surplus of income over expenditure has in most cases been realised. In those towns where gasworks exist the connections to the electric light mains are somewhat slow during the first year, particularly when the price of electrical energy is high. Consequently a proper conclusion cannot be drawn from the initial year's operations, but the connections increase as the electric light undertaking gives satisfaction to its customers. As an instance of this, the author gives a comparative table showing the growing increase in different towns from 1889 to December, 1894. A second table is given concerning the working results of the same and other stations. This table, an abstract of which is given below, represents, in percentage of the capital outlay, the surplus of receipts over expenditure during 1893-94, this balance remaining for the payment of interest and redemption. The figure of 4 per cent., as in the case of the Christiania electricity works during the year 1893-96, the author states, is sufficient for providing for depreciation.

	Receipts.	Expenditure.	Surplus.
Altona	12·6	5·56	7·04
Barmen	11·7	4·10	7·60
Breslau	23·98	9·02	14 96
Cassel	13·1	4·1	9·0
Christiania	13·1	4·90	8·20
Dusseldorf	9·92	2·94	6·98
Elberfeld	14·1	6·2	7·90
Neuhaldensleben	19·4	8·2	11·2

A direct proof of the commercial success of central stations, the author concludes, is afforded by the energetic endeavours on the part of promoters to obtain fresh concessions and to carry out electric lighting works at their own expense.

The Arc Lamp.—The first of three Cantor lectures on this subject was delivered on Monday evening by Prof. Silvanus P. Thompson before the Society of Arts. The lecturer, after remarking that much about the electric arc is still very obscure, discussed the question when and by whom it was first observed, and came to the conclusion that, in the first year or two of this century, Davy and other investigators found they could get sparks visible in daylight between well-burnt charcoal points connected each with a pole of the newly-discovered voltaic pile. These early experimenters did not clearly discriminate between a continuous arc and a succession of sparks, but in 1808 this distinction was certainly known. In 1820 the hard carbon deposited in gas-retorts came into use, and in 1846 the first mechanical arc lamp was devised. The lecturer then exhibited the arcs formed between various metals, and pointed out their different characteristics. He afterwards confined his remarks almost entirely to the arc produced between carbon conductors, carbon being the only material as yet known that is suitable for the industrial production of the electric light. He then proceeded to consider the physics of the arc. He discussed the conditions necessary for its formation, the point from which the greatest light is emitted, the relations between E.M.F. and length of arc and between amount of current and size of arc, the temperature of the crater, the fall of potential in the arc, and the question of the transfer of material from one carbon to the other, concluding, with regard to the last point, that material is transferred in one direction only—from crater to peak. He then showed an arc formed by an alternating current of 2,000 volts, though this, he said, was not a true arc, but of the nature of a flame. In the true arc there is combustion of the air with the production of carbon monoxide and dioxide, and of various nitrous compounds, whose smell may sometimes be noticed. In conclusion, Prof. Thompson referred to Duncan's researches into the effects on the arc of variations in the pressure of the air in which it is burning. As a rule, the temperature is raised by increase of pressure, and a higher E.M.F. is rendered necessary.

New Mains.—The London County Council have been impressed with the recent explosion in the Euston-road. The Westminster Electric Supply Corporation have given notice of their intention to lay mains across Norfolk-street and on both sides of Wood's-mews, Park-lane, in Palace-street and across it in two places, and across Stafford-place and across Francis-street in five places, and along the south side of it from Howick-place to Vauxhall Bridge-road. The proposed works are of the usual description, but the Highway Committee of the London County Council think that, having regard to the evidence brought forward at the enquiry into the cause of the recent explosion in connection with the electric lighting of the Euston-road, a condition that adequate ventilation shall be provided for the street boxes should be attached to the Council's consent. They accordingly recommended that the sanction of the Council be given to the works referred to on condition that the details of the street boxes to be used, showing adequate provision for ventilating them, be submitted to and approved by their engineer before the work is commenced, and that the covers of the boxes consist of iron frames filled in with materials to suit the paving. The House-to-House Electric Supply Company gave notice of intention to lay high-tension mains in Longridge-road. It has been stipulated that no pipes of a larger diameter than 6in. be used; that no street boxes be constructed until full details shall have been submitted to and approved by the Council's chief engineer; and that, as an additional precaution against accident through defective insulation of the mains, each of the street boxes be provided with an inner cover sheathed with wood or other non-conducting material, as well as an outer cover, the two insulated from each other as far as practicable, and that the outer cover be efficiently connected to earth. The same company intend to construct two transformer-boxes in Collingham-gardens and one in Barkston-gardens. The Charing Cross and Strand Electricity Supply Corporation intend to lay mains on the north side of the Strand, from the south-east corner of Trafalgar-square to the corner of Duncannon-street. It has been provided by the Council that the concrete floors

Digitized by Google

of the street boxes be 9in. thick and the York stone at the top 4in. thick, and that the longtitudinal girders (if used) in all the boxes be laid on 3in. stone templates the full thickness of the brickwork, which shall be 9in. thick. The Kensington and Knightsbridge Electric Lighting Company propose to lay mains and construct street boxes in Ovington-gardens and Ovington-mews.

Treatment After Electrical Shock.—The French Academy of Medicine having been asked by the Ministry of Public Works to draw up a set of rules for the treatment of those who may receive electrical shocks, a committee was appointed consisting of Messrs. Bouchard, d'Arsonval, Laborde, and Gariel. They have prepared the following statement: When a person is the victim of an accident due to contact with the electrical conductors or with the generators, the contact may exist when help arrives, or it may have ceased. In the former case, special precautions should be taken to break the contact without those helping becoming themselves victims. It is best to immediately stop the generating dynamo from working. If this be impossible, the current should be broken by cutting the conductor with instruments in which the cutting part is insulated from the handle, or the current is taken to earth or a branch by means of a conductor of low resistance, which will diminish the intensity of the current in the part where the victim is in contact with the principal conductor. These observations are merely made as a guide, and are to be formulated by a special technical commission instituted by the Ministry of Public Works. The following measures are proposed: The victim is to be first of all taken into an airy place; three or four persons should be there to assist, and no one else allowed to enter. The clothing is to be loosened, and efforts to be made to re-establish respiration and circulation as soon as possible. To re-establish respiration, recourse can be had to the following two methods—viz., drawing of the tongue and artificial respiration. In the former case the mouth of the victim is opened, and if the teeth are clenched they are to be opened with the fingers, or, if there be resistance, with a piece of wood, the handle of a knife, spoon, or fork, or end of a walking-stick. The front part of the tongue should then be taken between the thumb and index finger of the right hand, bare, or covered with, say, a pocket handkerchief (to prevent slipping). The tongue is then strongly pulled, and allowed to relax, in rhythmical imitation of respiration, at least 20 times a minute. These movements must be continued without a break for half an hour, an hour, or more. For artificial respiration, the subject should be laid on his back, the shoulders slightly raised, the mouth open, and the tongue free. The arms are taken at the height of the elbows, supporting them strongly on the walls of the chest, next bringing them above the head, describing the arc of a circle. These movements are to be continued at least 20 times a minute until the re-establishment of natural respiration. It is suitable to commence with the movement of the tongue as described, simultaneously, if possible, adopting artificial respiration. At the same time it is desirable to try and restore circulation by rubbing the surface of the body, by beating the body with the hands or with wet towels, throwing cold water on the subject from time to time, and applying ammonia or vinegar to the nose.

Telegraphy in Africa.—The report of the directors of the British South Africa Company, which has just been issued, contains the following information with respect to African telegraphy. In connection with the Matabele campaign a light field telegraph was erected by the Government between Palapye and Tati, a distance of 89½ miles. An office was opened at the latter place on January 22, 1894, and very shortly afterwards the line was handed over to the British South Africa Company, by whom it was extended to Ramaquaban, a distance of 17½ miles in a northward direction, where a temporary office was established on March 13, 1894. From thence a wooden pole line of a more permanent character was constructed, *vid* Mangwe, to Buluwayo, 105 miles, at which latter place an office was opened on July 9 last. The cost of this 105 miles did not exceed £30 per mile. It has been arranged that, in return for a payment of £1,000 a year, her Majesty's Government has the use of the wire for official messages to and from the company's offices in Matabeleland and Mashonaland. The lines between Tati and Mangwe, and between Mangwe and Buluwayo, were erected under the superintendence of the Cape Postal Department, and it has been decided, with the approval of the Government of that colony, that the Cape Postal Department shall, for purposes of common advantage, control the working of the company's service in connection with their own. Upon the line reaching Buluwayo, it was immediately decided to push forward the extension to Charter (*vid* the township of Gwelo), a further distance of 212 miles, and thus place Buluwayo in direct communication with Salisbury. It is anticipated that this branch will be opened for traffic before the close of the present month of January. In order to strengthen the chain of telegraphic communication northward, it has been decided to erect a short alternative iron pole line from Macloutsie to Mangwe, about 112 miles; this line is now in course of construction. A line will also be carried from Salisbury *vid* Umtali to Chimoio, the Beira Railway terminus, a distance of about 215 miles, thus placing Cape Town, Buluwayo, and Salisbury in communication with Beira. The total number of miles of telegraphs (exclusive of railway service lines) worked and owned by the British South Africa Company south of the Zambesi is now 1,225, and on the completion of the proposed extensions it will represent a mileage of 1,551. The revenue of the company's telegraph department, which, owing to the disturbances caused by the late Matabele war, only showed a net return for the 12 months ended March 31, 1894, of £370. 7s. 6d., now shows, after the pacification of the country, a net revenue of £2,755. 2s. 3d. for the six months ended September 30, 1894. It is interesting to note that during the month of October last, the gross revenue derived from the Buluwayo telegraph office was £526. 17s. 1d., showing the rapid growth and development of that town. Since the date of the last report good progress has been made with the work of construction by the African Transcontinental Telegraph Company, Limited, of that section of the line to Uganda which is to connect Salisbury in Mashonaland with the company's possessions north of the Zambesi, bringing Nyassaland, British Central Africa, and ultimately Lake Tanganyika, in direct communication with the Cape, and thereby Great Britain. The survey of the section from Salisbury to Zomba (400 miles) has long since been made; the material for the sub-divisions north and south of the Zambesi has been sent forward, and about 313 miles of line have been completed. This includes the section of 180 miles from Blantyre to Tete, and that northward from Salisbury as far as the Mazoe River, where telegraph offices have already been opened. An arrangement has been arrived at by the British South Africa Company, on behalf of the African Transcontinental Telegraph Company, with the Portuguese Government for the construction by them, with the telegraph company's material, of that part of the line, covering about 120 miles, which crosses Portuguese territory.

THE DESIGN AND EFFICIENCY OF PLANT FOR THE TRANSMISSION OF POWER BY ELECTRICITY.

A paper on this subject by Mr. W. C. Mountain, member of council, was read on Tuesday before the North-East Coast Institution of Engineers and Shipbuilders. The author first described the various units used by electrical engineers, and then detailed the construction and working of the dynamo and electric motor, this being followed by a table of the sizes, sectional areas, carrying capacity, etc., of cables. The author then proceeded as follows:

In laying down a transmission of power or lighting plant it is necessary to consider the loss of watts and volts in a cable, as it is very often necessary to proportion the size of the cable so that a certain number of watts or volts are lost, and the following rules will be of service:

Rules to Find the Loss in Volts in a Cable.—The volts lost in a cable of any length may be found by multiplying the resistance of the cable by the current flowing. It must of course be remembered in making this calculation that the distance between the dynamo and motor is doubled in the cable on account of the return conductor. If, therefore, the motor is half a mile from the dynamo, the total length of cable will be one mile.

Example.—To find the loss of volts in a $^{7}/_{15}$ cable—that is, a cable composed of seven wires, No. 15 L.S.G.—one mile in length, with a current of 29 amperes—*i.e.*, approximately 1,000 amperes per square inch section of copper—resistance of one mile of $^{7}/_{15}$ cable equals 1·498 ohms

$$1{\cdot}498 \times 29 \text{ amperes} = 43{\cdot}442 \text{ volts lost.}$$

It may be taken as a general rule (sufficiently accurate for ordinary practice) that there is a loss approximately of 2½ volts per 100 yards in cables where the current density is 1,000 amperes per square inch section of copper.

Rule to Find Loss in Watts or Volt-amperes in a Cable.—A further rule which will be of service in calculating the watts lost in any length of cable is the following: first, square the current—*i.e.*, multiply the current flowing in amperes by itself—and then multiply by the resistance, which will give the watts lost in the cable. For instance:

Example.—To find the watts lost in a $^{7}/_{15}$ cable when carrying a current of 29 amperes.

$$29 \times 29 \text{ amperes} \times 1{\cdot}498 \text{ ohms} = 1{,}259{\cdot}811 \text{ watts lost.}$$

It is therefore necessary, in estimating the size of generator required to drive a motor, to add to the actual watts required at the motor terminals the watts lost in the cables, and also the generator must be constructed to give at its terminals an E.M.F. equal to the volts lost in the cables, plus the volts required at the terminals of the motor. By suitably proportioning the size of cable to the work to be done, it is possible to make the power consumed in the cables anything that may be desired, but it must be borne in mind that by unreasonably increasing the size of the cable, and thus reducing the loss, a point is soon reached by which the first cost of the cable will be so high that the saving will not be economical.

Class of Cables.

There are, of course, many descriptions of cables suitable for transmission of power work—*i.e.*, as regards the insulating substance—but the writer does not recommend that any cable should be used with an insulation resistance of less than 300 megohms per statute mile. This is a suitable insulation for all voltages up to, say, 200; exceeding 200 and up to 600 the insulation resistance of the cables should be not less than 600 megohms per statute mile; and for a higher voltage, particularly if there is any damp, the insulation resistance should not be less than 2,000 megohms per statute mile. A megohm, it may be here mentioned, is the resistance equal to one million ohms, and the resistance of a cable is usually taken by immersing it in salt water for 24 hours, and then taking the insulation resistance between the conductor and the earth.

Various classes of insulating materials are used for the insulation of cables as under: (1) pure indiarubber, (2) vulcanised indiarubber, (3) vulcanised bitumen, (4) bitumenised fibre, (5) paper. Other substances have been used with more or less success, but the above may be taken to fairly represent the standard substances in use.

For lightly insulated cables pure indiarubber is sometimes used, but for general work the writer does not recommend this class of insulation, and strongly advises that vulcanised indiarubber be adopted as the insulating medium. Bitumen is largely used for colliery work, but cables of this description are generally armoured with galvanised iron wire or steel tape, and the writer would not recommend the use of bitumenised-covered cables except a protection of this class is used. Cables insulated with bitumenised fibre are also largely used for transmission plants, and Mr. Siemens in his paper before the Mining Institute showed a class of cable of this description which he used throughout his works. Bitumenised fibre is necessarily a substance which would very quickly absorb damp, and may be described as a mechanical insulating material, as it will mechanically stand a considerable amount of knocking about, and is only a thoroughly good insulating material when dry; it has, therefore, to be protected by being drawn into lead pipe, and may be then either braided or compounded outside the lead, or, as is most usual, armoured with galvanised iron wire or steel tape. The paper insulation has practically the same properties as the bitumenised fibre, and must be protected with lead, and if liable to injury must be further protected by galvanised iron wire or steel tape.

If it is proposed to run the cables along the workshop in casing, or to secure them by cleats or support them on insulators, then cables insulated with vulcanised indiarubber, or even pure indiarubber in very dry places, can be successfully used; but if it is desired to lay the cables underground, then they should either be lead covered, or preferably lead covered and armoured. Where cables are liable to mechanical injury—*i.e.*, in an engine-shop or a colliery—it is advisable to have them further protected by galvanised iron wire or steel tape, and the cables are generally further protected by a thick covering of hemp coated with preservative compound. It is advisable also to run the cables in wood casing, the casing to be grooved and fitted with a cover.

Efficiency of Motors.

Before any general scheme can be laid down, and also before the output of the dynamo can be calculated, it is necessary to take the actual watts required at the motor terminals, and to add to this the watts lost in the cables themselves conveying the current from the dynamo to the motors, and the following table is given showing the approximate efficiencies of electrical motors of varying horse-powers, with the watts required at the terminals of the motors at the efficiencies given, to produce one effective horse-power on the motor shaft:

Effective horse-power of motor.	Commercial efficiency. Per cent.	Watts required at terminals.
50 and upwards	90	829
40 ,,	88	848
25 ,,	85	878
15 ,,	80	904
5 ,,	75	995
3 ,,	70	1,066
1 ,,	65	1,148
½ ,,	60	1,244
¼ ,,	55	1,357
⅛ ,,	50	1,492

As an example, let it be assumed that it is intended to drive a motor 440 yards away from the dynamo—*i.e.*, a quarter of a mile—and the motor is to give 25 effective horse-power, with an efficiency of 85 per cent., the formula there is 25 effective horse-power by 878 watts per horse-power = 21,950 watts at motor terminals. The voltage at which it is proposed to work at the motor must then be assumed, and in this case let it be taken at 300 volts. Dividing the total watts—viz., $\frac{21{,}950}{300} = 73{\cdot}16$ amperes required to feed the motor.

It will be found that a suitable cable, assuming a current density of 1,000 amperes per square inch, would be wanted composed of seven wires No. 11 L.S.G. with a resistance of ·5776 ohm per statute mile, the length of the cable being half a mile—*i.e.*, to the motor and back—it therefore follows that the resistance of these mains would be ·2888

Digitized by Google

ohm. Taking the formula already given for finding the loss in watts in a cable—*i.e.*, multiplying the current by itself, or squaring it and multiplying by the resistance of the cable—it will be found that 73·16 amperes × 73·16 amperes × ·2888 ohm resistance = 1,546 watts lost. The

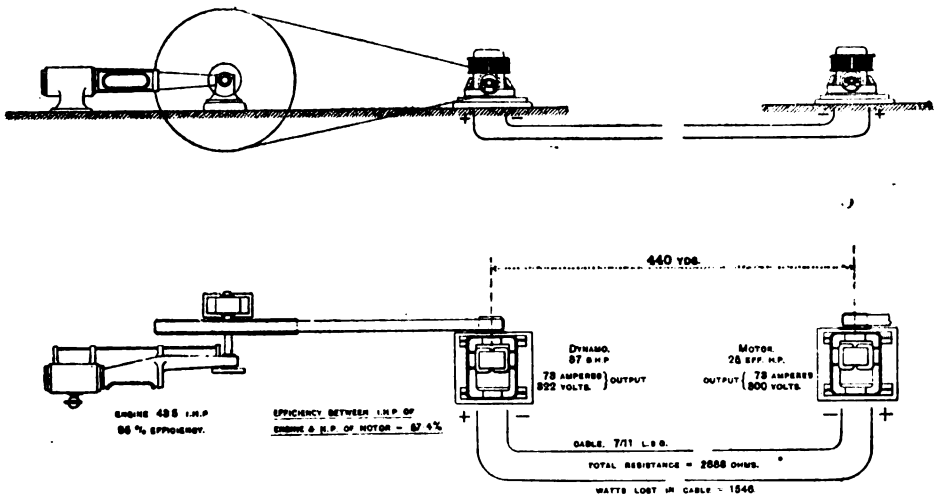

DIAGRAM I.

watts lost must now be added to the watts consumed by the motor, as under—viz. :

Watts consumed by motor	21,950
Watts lost in cables	1,546
Total	23,496

Therefore the generating dynamo must be capable of giving an output in watts equal to the above.

As the current was 73·16 amperes, all that is therefore necessary is to divide the watts required at the dynamo by the amperes, which gives the voltage at the dynamo terminals, say,

$$\text{Total watts } \frac{23,496}{73·16} = 322 \text{ volts at dynamo terminals.}$$

From the above it will be noted that the loss in the cables equals, say, 7 per cent. of the electrical output of the dynamo.

To find the total percentage of efficiency—*i.e.*, between the effective horse-power on the dynamo spindle and the effective horse-power given off at the motor spindle—the formula becomes, assuming an efficiency at the dynamo of 85 per cent., as under :

$$\frac{\text{Total watts of dynamo} = 23,496 \times 100}{746 \times 85} = 37 \text{ effective horse-power required to drive the dynamo.}$$

Assuming the efficiency of the engine driving the dynamo is 85 per cent.—*i.e.*, the difference between the indicated and the effective horse-power—the indicated horse-power of the engine will therefore be :

Effective horse-power required on dynamo spindle $\frac{37 \times 100}{85} = 43·5$ indicated horse-power to drive the dynamos.

Therefore the efficiency between the indicated horse-

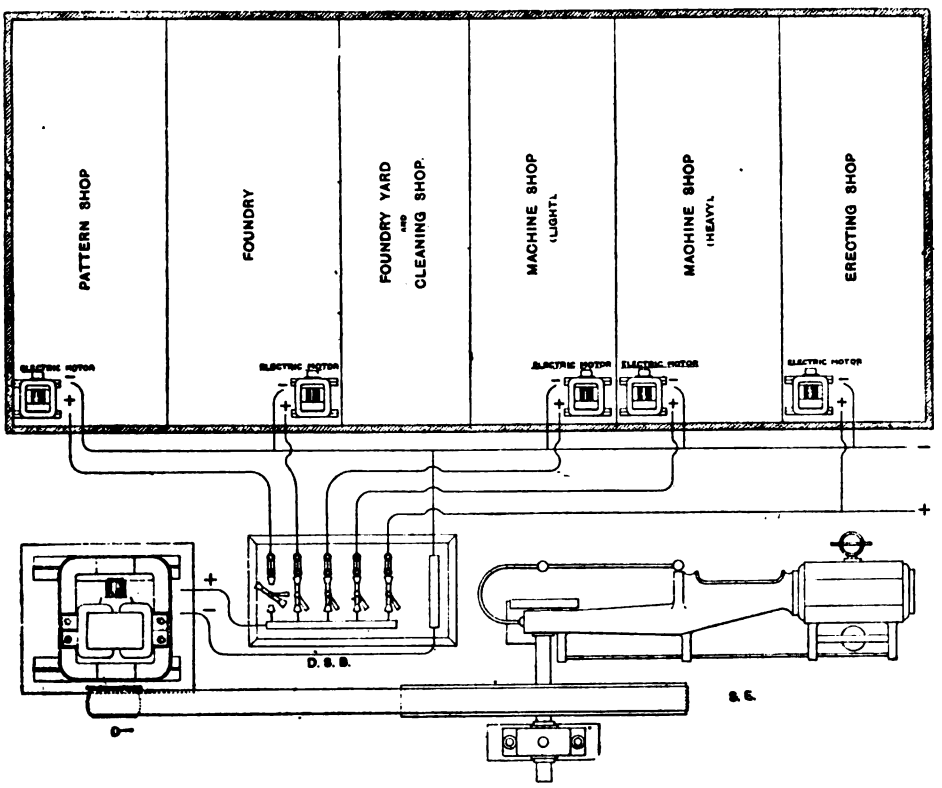

DIAGRAM II.

power of the engine and the horse-power given off at the motor spindle will be :

$$\frac{25 \times 100}{43·5} = 57·4 \text{ per cent.}$$

The writer trusts he will be pardoned for going so fully into this formula, but it is the formula by which the efficiency of any transmission of power plant is governed, and it will be necessary to apply this formula to any scheme which may have to be carried out, and he thinks it will be of value.

Digitized by Google

Diagram No. 1 represents the system described above, and on this diagram the sizes of cable are given for reference. Diagram No. 2 represents a transmission of power installation, and shows the method adopted where electric motors are fitted into each shop. On reference to the diagram, it will be noted that a horizontal steam-engine, marked S E, drives on to the dynamo, D. The current from the dynamo is taken to a distributing switchboard, marked D S B, and from this point five branch positive mains are led to five motors placed in the pattern shop, foundry, machine shop, heavy machine shop, and erecting shop, the negative mains being coupled together and returning to the distributing bar on the distributing switchboard. This diagram fairly represents the arrangement that would be adopted in a works where it is intended to drive each shop with a separate motor, and may be useful as indicating the general lines upon which a plant of this description should be laid down and the method of running the cables to the motors.

It would be an advantage in a system of this kind to have a separate ampere-meter to each circuit, so that the current flowing to any motor can be seen at a glance. This would be a further indication that the motors are working satisfactorily, and in the event of any particular motor taking more current than it should do under normal conditions, the excess current could be instantly checked and waste prevented.

Diagram No. 3 represents a transmission of power plant where separate motors are used for the large machines, and one motor for driving the line shafting for driving the small machines. On reference to the diagram the steam-engine is marked S E, the dynamo by D, and the main switchboard by M S B. From the main switchboard a pair of main cables are run round the shop, and the various electric motors tapped off in parallel, contact being made simply from the positive and negative mains to the positive and negative terminals of the motors. It will be noted from the diagram that the shops in question, and which may be taken as representing the machines in an ordinary machine shop, consist of two planing machines, one large face plate lathe, one large shaping lathe, and one drilling machine, each of these machines being driven by a separate motor, and six small lathes are driven by a motor which drives on to the line shaft, the lathe being fitted with the ordinary countershaft. From the above diagrams it will be noted that the principles upon which ordinary transmission of power plants are laid out is very simple.

(To be continued.)

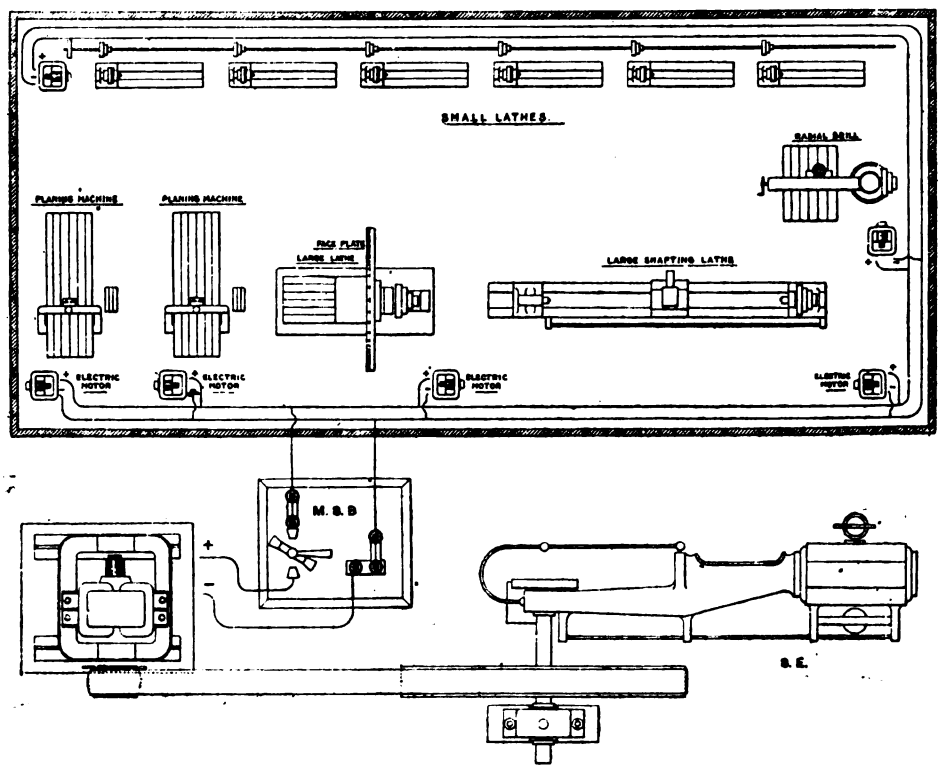

DIAGRAM III.

INSTITUTION OF ELECTRICAL ENGINEERS.

Inaugural Address by R. E. Crompton, M.I.C.E., President, Delivered at the Ordinary General Meeting, January 10.

I think that I shall interest you most if I address you on electrical engineering from my own standpoint. I believe that I am the first of your presidents who received his early training in mechanical and structural work entirely unconnected with electrical engineering, which at that time meant telegraph engineering. You must therefore not be disappointed if I deal with electrical engineering chiefly from the mechanical engineer's point of view, believing as I do that its great development dates from the time when the mechanical engineer first took in hand the design and construction of dynamo electric machinery. This date is that of the Paris Exhibition of 1878, so that we have had 16 years in which to develop the dynamo, the alternator, the transformer, and the storage battery into their present form. During these 16 years the dynamo, in mere size, has increased 500-fold, its efficiency has increased from 60 to 97 per cent.; from an instrument-maker's model it has become a machine which, whether as regards solid mechanical construction or smooth efficient working, will compete favourably with any form of engine or machine tool that has ever left the hands of the mechanical constructor. The modern alternator has been slowly evolved from the original Alliance magneto-electric machine, the transformer from the induction coil, the storage battery from the original Planté cell. When I say that the vast development which has taken place during these 16 years has been mainly due to the labours of the mechanical engineer, I do not in the least undervalue the immense labour of the physicists and of the telegraph engineers who preceded us; on the contrary, it is abundantly evident that this rapid development was only rendered possible by the splendid work which the physicists had already done, laying down so clearly the laws and the co-relation of E.M.F.'s, electric currents, resistance and induction, and to the admirable system of units which through the British Association Committee, the telegraph engineers had worked out to such completeness, that they now form, with very slight changes, the complete system of modern units that are universally adopted, and I cannot omit to mention the great impulse which was given to the progress of electrical engineering by the invention of the incandescent lamp by Swan, Stearn, and others. For it is quite certain that, although the development of dynamo plant for arc lighting and for transmission of power would have attained considerable proportions without the assistance which it has derived from the demand for incandescent lighting, yet it would have taken a vastly longer period to have reached its present stage of development.

I am one of those who, when I use the word "electricity," have before me a mental picture of an agency which we use for producing action at a distance, an infinitely flexible connecting

Digitized by Google

rod by which we can transmit energy and reproduce it at a distance in any desired form. Perhaps the reason why I have formed this mental picture is that I entered on the study of electrical engineering though a very correct process of evolution. Having been previously engaged on a practical application of hydraulic transmission plant, I was, from the time that I first commenced on electrical work, struck by the general resemblance which the flow of electric currents through conductors bears to that of water or other fluids through a system of pipes. It is almost a pity that the actual demand for electrical energy for light-giving purposes preceded that for mechanical power purposes, as the part which electricity plays as a connecting rod only is not so immediately evident when it is reproduced as heat for electric lighting as when it is reproduced as mechanical energy in a motor. At a very early stage in the mechanical development of electrical machinery, the mechanical engineer found himself confronted with an entirely new set of problems; he found that the laws which govern the flow of the electric current and the formulæ he had to use were simplicity itself compared with those he had been compelled to master before he could deal with the design of any form of thermal engine, or even deal with the flow of fluids or liquids through pipes, the chief reason being that the electric current is so easily confined—"canalised," as the French call it—in its conductor by its insulation that the losses due to electrical leakage may in most cases be neglected, whereas the loss in thermal engines through the walls of the passages or confining chambers are so great, and form such a large percentage of the whole of the energy, and vary through such very wide limits according to their form and to the materials of which they are constructed, that the calculations involved in any new design are extremely complex. On the other hand, the mechanical engineer found that the necessity for so frequently interposing insulating materials between the various parts of electrical machinery greatly increased the difficulties of mechanical construction. Nearly all insulating materials are deficient in mechanical strength; in most cases they do not maintain their form through any considerable range of temperature, are readily damaged by oil or grease, and do not readily lend themselves to being cut or shaped by ordinary tools. Constructors of electric apparatus have to deal chiefly with iron, copper, and insulating materials.

The improvement in the electric qualities of the first two have been very marked, and we have probably arrived at finality, but we have made but little advance in the improvement of our insulating materials. Probably of all the materials that are available for insulating or isolating the parts of generating machinery, transformers, and distribution appliances, mica is the only one that at all approaches our requirements, and mica is only satisfactory when it can be applied in thin sheets to insulate adjacent surfaces of considerable area. Slate, porcelain, and enamel, when used as insulators, although they can stand considerable changes of temperature without alteration of their insulating qualities, are deficient in mechanical strength, and cannot be readily shaped or cut. Wood, hard rubber, and the various patent materials—such as woodite, vulcanised fibre—although they are more satisfactory as regards mechanical strength, are considerably affected by heat, moisture, and oil or grease. The various slates and marbles are mechanically weak, and unless protected by enamel are absorbent, and partially lose their insulating qualities in a damp atmosphere. Attempts that have been made to mould or cast insulating materials out of mica waste or similar substances cemented together by shellac, resin, or other adhesive materials, have only obtained partial success. In no case has the double requirement of mechanical strength been combined with that of resisting change of temperature or the absorption of moisture. This difficulty in obtaining satisfactory insulating materials has been the chief stumbling-block which makes the work of the designer of electrical machinery so much more difficult than that of the designer of ordinary metal work, where the necessity for insulating the parts does not come in. The improvement of the material that must be used for insulating the distribution system of conductors has been an equally difficult matter. The study of this question was forced upon us as soon as it became evident that electrical energy could be commercially supplied and distributed throughout our streets. The problem has been attacked in various ways. The various systems of insulation that have been tried can only be tested by time; it will be many years before we shall be able to predict with any certainty as to which systems are likely to survive. It is impossible for me to devote more than a few lines to this interesting question. As you know, the systems of conductors that have been hitherto laid divide themselves roughly into built-in systems, drawn-in systems, and those which use bare conductors insulated by glass or porcelain. Quite recently the attention, not only of ourselves, but of the public, has been directed by several accidents to the dangers attached to electrical conductors laid in the streets. In many cases these dangers are not properly attributable to the electric conductors themselves, but to the presence of gas in the soil through which these conductors pass. Wherever any space exists into which this gas can infiltrate, an explosive mixture may be formed, which may be fired either by an electric spark from the conductors themselves, or by contact with a match dropped by a smoker. I think, however, that there is no reason for the public to unnecessarily alarm themselves. In the vast majority of cases where the system of conductors is continuously inspected for traces of gas, no accidents of any kind have occurred.

Although I have already stated that electrical engineering is greatly indebted to the mechanical engineer for much of the development that has taken place in recent years, yet in some respects the reverse is the case. The alliance between us has not been wholly productive of benefit to us. An electrical engineer nowadays has to grasp the whole subject of the production and distribution of electrical energy from the energy contained in the coal to the point at which it is delivered to the consumer. As regards a very large portion of the plant he has to use, the electrical engineer has had to adopt the appliances already sanctioned by the mechanical engineer: I allude to the boilers, steam-engines, and to the motive power generally. When the electrical engineer called for a motive power on a large scale, he found ready to his hand the experience of those who had equipped the great factories of the manufacturing districts of England; and these gentlemen have had a considerable hand in the design and application of the motive power we use, and I am afraid that in many cases the combination has not been altogether a paying one. Previously to the introduction of power-houses for the generation of electrical energy, the large mill-owners were the principal users of power in England, and it is to their requirements we owe the developments of the Lancashire boiler and the refinements of the large slow-moving engines that are always found in such factories. These gentlemen are perpetually reminding us that in order to obtain the maximum of economical success we have only to copy their practice, and that anything that differs from their practice is wrong; and I am afraid a very considerable number of electrical engineers, particularly the younger members of our profession, have been considerably swayed by these utterances. I feel very strongly, however, that it is time to speak on these matters with no uncertain voice. The conditions under which we work our engines, boilers, and other motive-power plant for electrical supply purposes differ so widely from the conditions of motive power for driving factories that their experience is of little or no value to us—in fact, it is in many respects misleading—and I take it to the credit of electrical engineers that it is we who have been mainly instrumental in developing the newer types of engines and boiler plant which are now largely used in our supply stations. I think that few will doubt it was the exigencies of electrical engineering that led the late Mr. Willans to carry out his extensive series of experiments on the economical use of steam which has so revolutionised our ideas on the subject. If it had not been for the conveniences for accurate measurements which the dynamo and electric measuring instruments offered, Mr. Willans's experiments could never have been carried out to the convincing degree of accuracy which he attained. I think, from this and from other causes, that we electrical engineers are already beginning to return to the mechanical engineers some of the benefits that we received from them. I am sure that the considerations of load-factor and all similar matters, which have been found of great importance to electric supply engineers, will be found to have almost equal importance in the matter of water-works, gasworks, and many other industries. In a word, I believe that the studies which we have been compelled to pursue in order to investigate and deal with our electrical difficulties will prove to be of considerable service to the engineering world in general, and that the engineering world in general will gradually become more and more intimately connected, so that eventually some part of the training of every engineer who deals with constructive works or supply works of any form will be an electrical one.

Not the lightest of the duties of the modern electrical engineer is that of educating the public in the use of electrical energy. This process, which we in this room call the improvement of the load-factor, is a matter of such importance to you all that I need not apologise for dealing with it at some length. We not only desire to have the output of our generating station more evenly distributed throughout the 24-hour day, so as to fill up the valleys and reduce the peaks of our daily diagram, but we also wish to improve the summer diagram as compared with the winter one. The problem of satisfactorily and economically working the daily diagram may be, to some extent, dealt with by improvements in the storage of electrical energy; but even if we were in possession of as satisfactory a system of electrical storage as the gas companies possess in their gasometers, it would only help us to this point. The great disparity between our winter and summer loads is due to our geographical position, and will always exist so long as the major part of the energy we supply is for lighting purposes, and the obvious remedy is to encourage its use for motive power and for heating and cooking; and to me at the present time it appears a far easier matter to educate the public to the advantages of using electricity for heating than to induce them to use motive power to any considerable extent. For this reason I have persistently advocated the perfecting

Digitized by Google

of electric heating and cooking appliances. This matter has not been much understood even amongst electrical engineers themselves. For a long time the opinion was very generally held that the energy required for electric heating is so great that its cost would be prohibitive. At first it was not seen how effectively electrically-heated appliances could be used for cooking purposes, how large a proportion of the heat units would be usefully employed in cooking food, and how small a percentage would be wasted in heating surrounding air. Now that this result has been obtained, and that cooking operations on a considerable scale can be carried on in an ordinary sitting-room without perceptibly raising the temperature of the air of the room, it will be seen that electric cooking is certain to obtain popularity in hot climates, or in summer, or in small tenements at such time when the lighting of fires and the waste heat from these fires is not only unnecessary but actually objectionable, and this even if the cost of the electrical cooking be considerably in excess of that by other means. At any rate, we may assume, if these expectations are only partially realised, that there will always be some sale of electricity for these purposes, and that the addition to our load diagram from such use will take the form of adding to it a parallel strip commencing from seven o'clock in the morning and ending at 11 o'clock at night, as I do not think there is anything in the condition of electric cooking to warrant anyone in thinking that the demand for energy for this purpose will be confined to the period immediately preceding each meal-time. The use of electricity for heating will be probably confined to the partial heating of rooms or parts of rooms which are required to be occupied for short periods or for the airing or warming of clothes or linen, and such use is also likely to be confined to the same hours as I have given for cooking.

Turning now to the possible extension of the load from the use of motive power, we know how large a portion of the income of the American supply companies has been during the past two years obtained from its motor load, and that up to the present our motor load in England, at all events in London, has been insignificant. I have attempted to find out, by putting questions to the managers of the most important American electrical supply works, whether the habits of the American people, or the construction of the dwellings in which they live or of their business premises, was such as to cause a special demand for motive power which would never arise on this side. It putting these questions, I fully expected to hear that their large motor load would be chiefly attributed to the driving of elevators, to the ventilating of their rooms during their exceptionally hot summers, and to the working of special machinery necessitated by their lofty buildings; but I am told that this is not so, that many of the large hotels and larger blocks of buildings possess their own separate plant for working their elevators and other machinery, and that the bulk of the motor load of the electric supply stations is obtained from the buildings of a moderate size, and that in these the motors are used for small industries and for domestic work, both of which uses are likely to exist to an equal extent in London or in any large English towns. If this is the case, we may feel sure that the commercial enterprise of those amongst you who make and sell electric motors and the engineers of our supply companies who are so desirous of increasing their motor load will be sufficient to make it gradually approximate to the American one. In this connection it is curious to note that although we in our central stations are so anxious to increase the output of our plant, and hence our load-factor, by encouraging the use of electric motors, the main argument we must use to an intending user is that of all sources of motive power none can be worked with so little waste of power during long periods of idleness as the electric motor. In other words, the electric motor is the cheapest of all systems of driving machinery when the load-factor is at its lowest. To mention a very ordinary case. Throughout all residential districts there exist a considerable number of small shops for repairing, and in some cases making domestic furniture on a small scale. In many cases it would be an advantage in such a small shop if one or two machine tools, such as a saw and a moulding machine, could be occasionally used for preparing the material. Such a machine would require from 3 h.p. to 5 h.p. to drive it when doing useful work. In most cases these machines would be only used for a few minutes at a time, several times a day, the total use probably not extending to more than seven hours per week. If the user obtained his power from a central source of supply, and paid 4d. per unit for it, the total cost of working these two machines would only be about 7s. per week, although the above time would be made up of many short periods of use. If we add on an ample sum for the interest on the cost of the machines and motors, and for their maintenance, the total cost need not exceed £1 per week, so that it is evident that in many cases it would pay well to employ such tools and motors, rather than send work out to be executed at a sawmill. It is evident that if the same intermittent employment of power had to be obtained from a steam-engine or even a gas-engine, the total cost of full attendance and upkeep would be from £3 to £2 per week, quite apart from the many inconveniences and dangers attending the use of steam power in small premises. It is evident, however, that as you increase the hours during which these machines are worked, the electric motor will lose its advantages, and a point will be reached at which, first the gas-engine, and eventually the steam-engine, will be found to compete favourably as regards cost.

This argument of the cheapness and convenience of the electric motor for very intermittent supply of power is one which cannot be impressed too strongly on likely future users of power; but apart from what we can do in supplying power to such small industries, there is much to be done in this country in familiarising the minds of the inhabitants of Mayfair and Kensington—to take these districts only as typical of many others—that the use of motive power in private houses need not be limited to working lifts, driving sewing-machines, knife-cleaners, grinding coffee, or even, as has been stated in another presidential address, "brushing their boots, washing their faces, and serving their meals." With great deference to the gentleman whose words I have just quoted, I must submit that there has hitherto been a certain want of imagination shown whenever the question of the possible extended use of motors has been discussed. No one can help noticing that amongst English women and English men, at any rate, the desire to work at home, to make something useful or artistic, or to decorate or to beautify our homes, is very widely spread. The number of those who employ their otherwise idle fingers during their leisure time in some kind of work is very great, but hitherto this work has been confined to sewing, embroidery, etching, painting, light carving—at any rate, to work where the muscular exertion required is small. This practically excludes any constructive or decorative work which requires to be made out of materials of a hard and enduring nature, but if once the electric motor is pressed into our service, if the electrically-driven shaper or graver needs only to be intelligently directed by the user, the most delicate-handed lady could cut and carve out designs in the hardest materials with the same ease and same certainty that she now uses the embroiderer's needle or the etching pen. There is one use to which electrical energy can be applied in very considerable quantities in residential districts. I allude to the production of artificial cold by means of electric motors. You all understand that this is at present done by arranging them to drive an air-compressor, and afterwards expanding the compressed and already cooled air into any properly constructed cold room in which it is desired to maintain a temperature sufficiently reduced to store perishable eatables—such as meat, fish, game, and vegetables or fruit—for long periods. Such cold storage would enable each consumer to deal far more directly with the producer than has hitherto been the case; the cost of several daily deliveries of food articles would be practically abolished, and the extravagances and waste of housekeeping would be reduced to the lowest possible limit; in fact, the advantages of such cold storage are so obvious that it is unnecessary to further insist upon them.

There is another development of the use of electricity for motive power to which I think your attention should be directed. The president of the Institution of Mechanical Engineers, in his address to the mechanical engineers in April of last year, drew attention to the efficiency that we claim for electric transmission of power to machine tools, and compared it with the efficiency of existing systems. I have Prof. Kennedy's permission to use his address as a means of carrying this highly interesting problem a step further. He said that "in any given factory running on the ordinary system there is a large continuous waste of power due to the running of the whole shafting, no matter how many or how few are at work; under such conditions the waste work in shafts and belts may well be 25 per cent. of the average useful work, and the distribution of total work may be approximately:

For the useful work	100
Wasted in belts	25
Wasted in engine friction	20
	145"

He compared this with an electric transmission as follows:

Useful work	100
Wasted in motors and dynamos	24
Wasted in leads	2
Wasted in engine friction	20
	146

So that he shows that the two sets of figures are practically the same as to amount of power required. I think that the cases where the comparison would work out on such equal terms would be very rare indeed, and would only be likely to apply to textile or similar factories. In engineering shops, where the time during which each machine tool is standing for the work to be fixed is very large compared with the time that the tool is actually running, I think it would be not too much to say that n most such shops the useful 100 h.p. he gives in his first table

Digitized by Google

might be divided by 3, the other losses remaining constant, so that the average useful effect throughout the day is not as 100 : 145, as given by him, but rather as 33 : 78 ; in other words, the average efficiency, instead of being 68½, would be really about 42 ; but in such a case, if electric transmission with separate electric motors for each tool be used, the efficiency can remain at 68 as before. Therefore I believe that the cases where electric transmission of power can be substituted with considerable advantage over present systems are far more numerous than Prof. Kennedy's figures would lead us to suppose. It will be noticed that the difference between my assumptions and those of Prof. Kennedy lies chiefly in our estimates of the load-factor of each of the tools.

Several times when addressing you here I have used the term "load-factor" to denote the ratio which the total useful time during which the appliance is worked discontinuously bears to any given period, whether it be an hour, a day, or a year. As you know, I found myself compelled to investigate this question when dealing with the cost of electrical energy in my paper before the Civil Engineers ; but this load-factor question has a far wider application. If any attentive observer walks round a factory where machinery of any kind is being used, and takes careful note of the relation of the periods of useful work of each mechine to its periods of idleness, he will be struck by the large proportion which these hours of idleness bear to the hours of usefulness. As regards the machines themselves, the only loss caused by these long periods of idleness is that due to the interest on the money invested in them ; but in the case of the engines which drive them, or of the transmission devices, such as shafting or belting, in addition to the loss of interest, there are continuous losses due to the waste of power and cost of attendance that is required to keep them in motion at the required speed during these idle periods.

This matter is of great importance to us electrical engineers, for of all methods of transmission of energy that now exist, none can be worked with so little waste of power during these periods of idleness as electrical transmission. I have already shown this to be the case where the source of power is obtained from an electric supply station, and it is certainly the same in any works where any considerable number of tools are required to be intermittently driven.

One of the chief difficulties that have been met with in replacing the muscular energy of ourselves or of animals by that of the forces of Nature has been that of providing a variable ratio between the two factors of speed and torque that is necessary if we have to obtain from a constant source of energy the varying duty that we usually demand from our muscles. All our machine tools are provided with a few changes of the speed gear which forms a clumsy approach to this requirement. I have sought in vain for a short expression to define such a variable gearing, but am obliged to content myself with calling it "speed torque ratio gear." In all attempts to carry this out mechanically the change of ratio can only extend through very narrow limits, and at the outside four or five steps in the change of ratio can be given. Mechanical engineers for many years have been looking for such a gearing which will vary the ratio exactly as required, and not by steps. The nearest approach to this has been by two reversed cone pulleys with a round belt of constant length, which is moved or retained in any desired position by a fork sliding in guides. Quite recently Mr. W. W. Beaumont has introduced a mechanical variable ratio gear which is a decided improvement ; but in my view the first real step which promises to revolutionise our ideas on these matters has been the working out of this problem in the electrical portion of our plant—*i.e.*, in availing ourselves of our really flexible connecting rod, electricity itself.

One arrangement of this kind has been worked out in America by Mr. Ward Leonard. If it is desired to provide from a constant source of energy at the axle of the motor, C, either great torque at very low speed, or the same energy in the form of reduced torque at the higher speed, this is done by Mr. Leonard by passing the energy through a motor generator, A B, the motor, A, of which may be either an electric motor driven from a central station, or a steam, gas, or water engine, but in every case delivering a constant supply of mechanical energy to the spindle of the generator portion, B, the armature of which is connected by short conductors of low resistance to the motor C. If the magnets of motor C are kept supplied with a constant field from a constant source of supply, and the magnets of the generator, B, receive a variable degree of excitation by inserting a rheostat in series with them, so that the field may be varied through wide limits, by commencing with an extremely weak field in the generator, B, the motor C can be started with a large current, giving large torque at low E.M.F., then as the excitation of the field of B gradually increases, the E.M.F. of the generator and of the motor will also be increased, and at the same time the torque diminished, so as to get the spindle gradually into motion, and the machine driven by the motor C steadily brought up to its proper speed.

I give the description of this beautiful electrical gear just as it is given to me, and am told that there are no difficulties found in working it in actual practice, but I feel sure that it is only one of many similar methods by which this variable torque and speed ratio can be worked out electrically, and with a simplicity in the moving parts resembling that of the muscular system of the animal world. The application of this invention to working long lines of railway would appear to get over the great difficulty which would be due to the heavy fall of potential which occurs at the times when large currents are taken by the ordinary train motors whenever a train starts from rest, this difficulty being only slightly reduced by the device of motors arranged in series, and afterwards switching them into parallel. With Mr. Leonard's arrangement a long line may be worked at a high E.M.F. of 10,000 volts, generated by monophase alternating machinery, transformed at intervals and supplied to sections of the line at an E.M.F. sufficiently low to be easily dealt with—say, 500 volts—but still in the form of an alternating current. This alternating current could be collected from the line and used to work the motor A, as the arrangement I have just described would allow that this motor A should be a monophase synchronising motor, worked at extremely high speed, and having the generator, B, driven by it ; the generator, B, and the main motor, C, would be of the continuous-current type, and there is no reason why the motor C should not be of extremely low E.M.F., and consequently easily made direct-acting on the driving axle.

I have described this invention at some length, for, although it may have been noticed by some of you, it has probably escaped the notice of many who are engaged in thinking out the interesting problems of electric traction, haulage, or other uses to which the use of electric power is every day being applied.

We electrical engineers are frequently complimented on the perfection to which we have brought our measuring instruments, and in most cases this praise has been fairly earned, but I think some protest should be made against the very impossible degree of accuracy which is often claimed for electrical measurements. Such claims for accuracy those more thoroughly conversant with the subject know to be unwarranted ; they arise from an incomplete appreciation of the difficulties which attend the making of very accurate measurements of any kind. We often see the efficiencies of the various classes of electrical apparatus worked out to several places of decimals, when it is well known that no instruments exist which could record the measurements to this degree of accuracy. Electrical measuring instruments depend in the majority of cases on the accuracy with which they can indicate the amount of the minute forces to which their moving parts are subjected. In order to make them as sensitive as possible, these moving parts must be delicately adjusted or suspended, and the accuracy of the readings depends entirely upon the degree to which the instrument can be depended on to reproduce exactly the same readings under the same conditions as those observed when it was originally calibrated. It is evident, however, that this accuracy can only be maintained if the friction of the parts and their correct position and the strength of the controlling forces remain exactly the same as they were at the time of calibration. In practice it is found impossible to guard against minute changes in these conditions ; so that, however accurately the instrument of precision may be calibrated in Scotland, the very delicacy of its pivoting or suspension, which are necessary for accuracy, make it quite certain to lose its correct calibration after a journey to London, and no one could swear to the correctness of the readings. The case becomes worse if such instruments have to be used as travelling standards of reference. Take the very common instance of an inspecting engineer going to a maker's works to test the efficiency of a steam dynamo, the passing of which may depend on 1 per cent. of efficiency. In order to simplify this matter, I will suppose that there is no dispute as to the measurements of indicated horse-power, but that it is confined to the difference between the electrical readings of the maker's instruments and those of the inspector. One per cent. error in the readings of either current or volts, or ½ per cent. error in the readings of both of them, is sufficient to reject the machinery. How is it possible for an inspecting engineer to avoid dispute? How can he say that he feels more confidence in his instruments than in those of the maker? The balance of probability is that the maker's instruments, having remained *in situ* since their calibration, are less liable to error than the travelling instruments, which may have received shocks during their journey. If, however, the dispute had not been an electrical one, but had turned on questions of size or weight, the size measurements would have been easily dealt with by the ordinary steel rules in the shop, which can generally be depended upon to one part in a thousand ; and the weight would have presented no difficulty, as, if an ordinary beam balance were available, it could be adjusted in the presence of both parties, or, at any rate, the positions of the standard weight and of the object to be weighed could be exchanged, so that the mean of the weights thus taken would give the correct result. I have always thought that all important and accurate electrical measurements should be as easily checked and referred to a standard as the measurement of weight can be in the beam balance, but no existing measuring instruments having moving

Digitized by Google

parts can be thus easily checked. For this reason, for the past eight years I have been attempting to reduce all electrical measurements to a balance of electrical forces—that is to say, by referring them to a standard fall of potential obtained on a carefully calibrated slide wire—in other words, the potentiometer. I have occupied much of my leisure time during the above period in perfecting this potentiometer system, which is already well known to most of you. I only mention it here in order to point out that with this instrument there are no moving parts, and that the only calibrated portion—the slide wire—can be subjected to extremely rough treatment without altering the accuracy of the instrument to any material extent. Once this slide wire is accurately divided, and that portion of it on which the sliding contact works is made of equal and even resistance per unit length, and is stretched rigidly over an accurately divided scale, it is almost impossible for the instrument to lose its calibration, short of actually severing the wire; and even if the wire is severed, a new wire can be applied and calibrated without the necessity of sending the instrument home to the maker, or to any standard laboratory, in order to compare it.

Whilst on the subject of electrical measuring instruments, I must not neglect to notice that very beautiful instrument, the bolometer of Prof. S. P. Langley, and its recent developments in the hands of Messrs. Lummer and Kurlbaum. The bolometer is really the most refined method of measuring temperature that has yet been proposed. Its readings are obtained by measuring electrically the varying resistances of a platinum film when submitted to minute changes of temperature. It is, in fact, Siemens's electric pyrometer, or Callendar's platinum thermometer, in its most complete form.

I should also not fail to call your attention to the splendid work of Prof. Callendar and Messrs. Griffiths and Clark in perfecting the platinum thermometer. By the aid of this instrument, and by electrical means, Messrs. Griffiths and Clark carried out the most recent determination of J, the value of the mechanical equivalent of heat. In my own practice I have found that the ease with which the platinum thermometer can be used in connection with my potentiometer system has given to me the most accurate, sensitive, and convenient methods of measuring temperatures in the various electrical apparatus which I have to examine. Anyone who possesses a potentiometer can take almost simultaneously any desired number of temperature readings by employing a number of platinum coils all made equal in resistance to an external standard with which they have been compared and adjusted at the temperature of melting ice. The external standard must, of course, be of manganin, which at ordinary temperatures has practically no temperature coefficient. If we adjust our potentiometer so that the readings on this standard are equal to 100 on the scale, the readings taken over the various platinum coils that are coupled in series with it will give directly the percentage rise, from which the temperature can be read off on a table calculated from the temperature coefficient of that batch of platinum wire.

I do not know if this beautiful method of measuring temperature is generally known to electrical engineers who are investigating such matters as the changes of resistance due to changes of temperature in insulating materials, the rise in temperature of the various parts of dynamos, transformers under varying conditions of load—in fact, in the everyday quantitative work of the electro-dynamic designer.

I have stated that in my researches I have adhered rigidly to the principle of making accurate electrical measurements by obtaining a balance of E.M.F.'s—in other words, by using a zero method. I should here explain that there are two zero methods—namely, that obtained from the simultaneous balancing of two forces, as in the Wheatstone bridge or any other split-circuit device; the other, by balancing each of the two forces in turn (*i.e.*, the one to be measured and a standard with which it is to be compared) against a third force, the two comparisons being made as quickly as possible one after the other. This is the zero method that I prefer, as it avoids the very great possibilities of error, which I find are likely to arise whenever divided or shunt circuits are used. With this latter method the determination of several falls of potential can be obtained off different portions of the same circuit through which one and the same current flows in series. One can be certain that, apart from the minute variation due to the difference of time, the conditions of current-flow are absolutely identical. From my point of view the only permissible use of shunt circuits is in the potential leads attached to the two points, and by means of which the difference of potential is measured; but a circuit through these leads cannot strictly be called a shunt to the main circuit, for, although a small current may be passing through it before perfect balance is obtained on the potentiometer, as soon as such balance is obtained absolutely no current passes through this potential lead circuit, so that any change in their resistances, or in the resistance of their contact with the standard conductor, does not affect the readings. For accurate measurement of large currents we use sheets or strips of suitable alloys, so as to reduce the correction for change of resistance due to change of temperature as far as possible. The copper-manganese nickel alloy called "manganin" has turned out to be very useful to us in this respect. It has the great advantage of having a falling curve between the temperatures of 30 and 70 centigrade, and can consequently be compensated by being combined with a metal having a rising curve, in such a way as to produce a standard having no temperature correction necessary between the above limits.

No doubt you will expect me to say a word on the subject of electric storage. Although comparatively little has been written or said about the improvement in the design and manufacture of the lead secondary battery invented by Planté, yet the progress in its development has been quite as marked and quite as satisfactory as that of the dynamo machine or alternator. I do not allude to new patterns of accumulators which claim to be new inventions, but solely to the improvement in detail and in manufacture which has followed on the competitive use of well-known existing forms. No doubt one reason why members of this Institution are not kept as well informed on the development of the storage battery as on other subjects is, that the questions involved, being electro-chemical ones, are extremely complex, and require long periods of time for their thorough investigation. Moreover, I regret to say that a dead set has been made at accumulators by some members of this Institution, who never rise in their places to mention them otherwise than by a sneer. It is curious this should be so. The secondary battery demands as high qualities for its patient investigation as does any other branch of electrical engineering; and those who are never tired of telling us that they cannot see the importance of improving electrical storage as much as that of any other portions of electrical plant, only show that they have a very incomplete grasp of the requirements of our art. At any rate, if we can judge from cost price and from cost of upkeep only, the advance in the construction of accumulators during any period—say, the last 10 year or last five years—has been quite as rapid as that of the advance of the construction of dynamo-electric machinery. A reference to the price-list of makers of dynamos and accumulators will show that this is the case, and from my own knowledge I can state that recent improvements are reducing the cost of maintenance to an equal extent. The study of the proper application of accumulators for electric supply is not confined to the design of accumulators themselves, but to the many adjuncts necessary to use them to the best advantage. The difference between the E.M.F. of charge and discharge has been satisfactorily dealt with by the various booster systems that have been introduced during the last two or three years; and the proper proportion which the output of the accumulators themselves should bear to that of the station, and the most economical size of generating unit to charge these accumulators, have also been carefully worked out.

It is probable that most of the early troubles with accumulators were due to want of knowledge of the necessity for extreme purity in the materials used. These impurities concentrated themselves in the active material on the negative plate and caused the now well-known phenomenon of self-discharge of the negative plates, which of itself is sufficient to account for the majority of the early breakdowns which at one time appeared to be so mysterious. We know how important it is for dynamo construction to have iron absolutely free from manganese and copper from arsenic, minute quantities of these, which could hardly be detected by chemical analysis, having the effect of largely altering the permeability of the iron or the conductivity of the copper. No less it is the case that minute quantities of certain metals, such as copper and arsenic, have an equally prejudicial effect in the lead used for accumulators; and the discovery of this effect has had a most important effect on the cost of manufacture and the cost of upkeep.

I feel that I should be failing in my duty towards you if I did not raise a note of warning on a point on which I feel very strongly. Owing to a combination of causes, the chief of which has been the great extent to which public money is now being spent on electrical supply undertakings, the control of large sums raised on the security of the public rates has been placed in the hands of very young engineers whose engineering life and experience has been a very short one. I am afraid that in some cases the extent of their responsibility has not been as fully realised by these gentlemen as it ought to have been. Local and special requirements have been insufficiently studied, designs have been hurriedly prepared, the *pros* and *cons.* of the various systems which could be used have been inadequately balanced, and I feel great misgivings as to the criticism that will be passed on these hurried designs after a few years have passed. I go further than this. I think that in many cases failure in part or in whole will follow, and so soon as this takes place a reaction will set in which will damage the interests of our profession almost as much as the speculation in electric light companies' shares in 1882. We all know, or ought to know, that an electric supply system, to be successful, ought to be worked out from beginning to end as a complete scheme, with due regard to the special conditions of the town as to probable light and power requirements, and to the habits of the people; and that this is a very different thing from the mere preparation of a design

Load Curve, showing the Combined Output of the whole of the London Central Stations during the 24 hours ending at 6 a.m. on the 20th December, 1894.

for a building containing some plant, for laying a few miles of mains in the principal streets, with variations in the shape of providing power from the dust destructors or utilising thermal storage, in order to humour the vagaries of those of the electric lighting committees who fancy themselves engineers. I fear that this Institution is in some degree to blame for this: the papers that have been read, discussions that have taken place, have turned far too often on purely scientific matters, of interest only to the scientific men who took part in them; and that this has thrust into the background the more prosaic matters, which must be studied by those who hope to deal thoroughly and economically with the many and varying conditions of electric supply.

I hope these remarks will be taken in the sense that they are intended to be taken. It is even now not too late for those who are already carrying on works to inform themselves more fully than they have hitherto done on what is going on around them, and on the respective merits of existing electrical engineering practice. I know that many of those who are now so engaged, and who are responsible for the designs of the supply works that are now arising throughout the United Kingdom, and many of those who are now on the look-out for such employment, are setting out insufficiently equipped for their task; they have, I fear, studied their subject too much as book students, and have not spent sufficient time on travel and on the careful study of electrical machinery as it exists in England, the Continent, and America. As an engineer intimately connected with the management of several important supply works, I know that the number of young engineers who really attempt to practically examine and study the working of existing supply works is small. If I ask the engineers in charge of these works how often they receive visits, or have really serious enquiries addressed to them on these matters, I am answered that such enquiries are practically not made; in fact, I am afraid that the interchange of ideas, the comparison of experiences in the use of various novel kinds of plant, the exchange of statistics, exists chiefly among us the older members of the profession, and that although we are most willing to impart what we know to our younger brethren, we are practically never asked to communicate the results of our experience.

I hope also that what I am now saying will not be put down to the natural conservatism or grumbling of an older man dissatisfied with the existing order of things. Think the matter over for yourselves; compare the length of time that you have occupied in your training, and the number of years' experience that you have in your new profession, with that of the engineers employed in other branches of engineering who are put in charge of undertakings of equal importance. However brilliant may be your talents, you cannot hope to acquire that unerring critical faculty that power of rapid decision between two methods that offer themselves to you, of dealing with an engineering difficulty, and which was so ably described and put before Section G at the last meeting of the British Association by one of our members—the president of that section, Prof. Kennedy—until you have added years of practical observation to your training as a pupil, or your workshop experiences. I feel sure that Prof. Kennedy will allow me to quote his own words: "The whole use of college training, of workshop practice, of practical experience, is to provide the engineer later on with the means of critically examining each question as it comes up, of reviewing systematically the *pros and cons.* of each method of dealing with it, of coming finally, rapidly, positively, to some definite condition, which may then be irrevocably carried out."

I am now addressing the whole body of electrical engineers, old as well as young. None of us are too old to learn and profit from the experience of others—in fact, as I have already said, I find that such interchange of ideas as now exists is far more among the older than the younger members of our profession. This is much to be regretted. It may be partly due to the diffidence or shyness of the young men, but I greatly fear in many cases it is due to their fear that their crude and hastily formed ideas may be adversely criticised. Never during the 16 years which I have named as the life of our art have there existed more momentous questions to be solved than at the present moment; and, if I can by my words induce a freer interchange of ideas, so that we help one another more than has been done in the past, I shall feel that I have been of some service to the Institution. Such interchange takes place most naturally in the tea-room after each of our discussions. I think the time spent in the tea-room is very valuable, and is far too short; and I think the practice, recently started by the Institution of Civil Engineers, of prolonging the evening meeting in the form of throwing open several rooms in which may be exhibited models of new instruments of interest is a good one, and might be with advantage copied by us. This time after the meeting is often much curtailed by the length of the discussions, and I hope that you will support me in the chair when I try to shorten the discussion, particularly when it runs away on matters irrelevant to the paper of the evening.

The ideal method of best spending the time of the session is in discussions on the points of most interest to us at the time—*i.e.*, on burning questions which might be started by comparatively short papers, printed and distributed before the discussion, so that the whole evening might be devoted to it. I, for one, hope that we shall have free, fearless, and open discussion on all matters which affect our art. Let us keep away from any imputation of personal motive, but at the same time let us not hesitate to condemn as well as to praise, simply because such condemnation may appear to hurt the commercial interests of A, B, or C. I say advisedly "appear," because honest criticism in most cases is likely to prove to the advantage of A, B, or C, as it may open their minds to matters which they had never had fairly put before them.

After such a long spell of what I am afraid you will consider too plain speaking on my part, I end my address by calling your attention to the diagram on the wall which shows the combined output, or load, of the London electric supply stations for a night in December, 1894, and which was taken simultaneously for the purposes of this address, and for which I have to thank the engineers of the supply companies. I have not had the opportunity to compare this with the load of any other city in the world, but I fully believe that it will be found to be one of the largest that has ever been drawn out—at any rate, we electrical engineers, with such a diagram before us, can point at all events to the very substantial degree of development of supply of electric energy in London.

I have to thank you for listening patiently to what, after all, is a recapitulation of facts which have been already known to many of you. I can only hope that they were not known to others, and that they may be of use to them.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

CITY AND SOUTH LONDON RAILWAY.

Although the accounts of this pioneer underground electric railway have not yet been published for the past year, the company state, as announced in another part of the present issue, that for the half-year just ended the full dividend of 5 per cent. is available for the preference shares, whilst the accounts for that period allow of a dividend at the rate of 1¼ per cent. per annum on the consolidated ordinary stock. To say the least, this is a fairly satisfactory result. We say fairly satisfactory advisedly, because the company, in making a new departure in underground railway working, have been hampered by having, as it were, to work in the dark; but the experience gained in the operation of this short line will, it is to be hoped, eventually result in the bringing in of a substantial commercial return. Already the practical working of the railway has suggested certain improvements which the directors propose to carry into effect. One of these is in the direction of conveying additional passengers during the busy portions of the day, and for this purpose, as we stated some time ago, experiments are being made with carriages equipped with electric motors in preference to the employment of separate locomotives. By this means it will be possible to run a train composed of four coaches, the limit of the length of the station platforms at the present time being three and a locomotive. It would not be far wrong to suggest, apart from the electrical equipment, that if the company had to redesign the general construction of the line, considerable modifications would be introduced.

As to the dividend of 1¼ per cent. on the ordinary stock, this is an improvement over that in the corresponding period of last year, when it was at the rate of ⅝ per cent. per annum. In fact, the company have profited by four years' working experience, of which, it is needless to say, the promoters of similar undertakings in the Metropolis have taken advantage. The company have paid on the ordinary stock dividends of three-eighths, five-eighths, and five-eighths for the past three years, and the promise for the fourth year's operations is more hopeful. At the same time the line has had to pay for being a pioneer, and although a slight improvement is taking place, very material progress does not seem possible until the extensions to Clapham Common and to Islington have been carried out. When these have been accomplished, as we hope they soon will be, we look for a larger amount of traffic proportionately and to better returns.

TRANSFORMER-CHAMBERS.

As anticipated in the comments made in our editorial columns on the 7th ultimo, the Board of Trade has now formally intimated its decision upon the above subject to the London County Council, and other interested parties, in a manner favourable to the electrical industry, and in very much the same terms, moreover, as were employed by Sir Courtenay Boyle to explain the advice he proposed

Digitized by Google

to give the Board upon the termination of the recent enquiry into this matter.

The essence of this decision is contained in two statements: first, that the expressions in the provisional orders with regard to boxes for regulating or controlling the supply of energy must certainly be held to include, if not specifically refer to, the appliances and means for transforming energy, and, therefore, transformer apparatus can properly be dealt with by the Board of Trade under the provisional order. The second statement sets forth that there is practically no limitation with respect to the size of the boxes—consistent, that is, with due regard to other users of the public streets.

As a matter of common sense, the decision of the Board is, of course, just what might have been expected. Whilst the electric lighting interests are undoubtedly justified on both technical and business grounds in avoiding private property for their transformer-chambers, yet it would hardly be proper that street-chambers should become actual sub-stations, and, therefore, due limits are set down for general use, to be modified or extended by the Board in dealing with particular cases. It is hardly conceivable to suppose that the use of such boxes or chambers should be altogether forbidden in London, for they are so devised on the score, not only of economy, but also convenience and safety—however much the latter may be disputed. Without doubt the London local or central authorities would themselves have followed the same course as that already adopted in this way by the electric lighting companies (and approved by the Board of Trade), if the former had undertaken the supply of energy in the first instance. Other towns and municipalities freely adopt the use of transformer-chambers in the streets, and find no trouble arising therefrom. Of course, we do not touch upon the legal powers which might or might not be thus handed over to the electric lighting companies, though a right of user for beneficial purposes ought surely to be granted at once without dispute—at a peppercorn rental, for that matter, if objections are felt on the score of taking way-leaves for nothing.

In every respect, therefore, the decision of the Board of Trade is an excellent one, and greatly to be commended. Perhaps the electric lighting companies have not obtained *all* that they would naturally desire, but some consideration is of course due to other public services, and hence the limits now defined. We do not see what the local authorities can find to object to in the present status. In many continental cities the transformer-chambers are not put underground, but are actually on the street or pavement level, enclosed in large and massive iron pillars like exaggerated street letter-boxes. What would be thought of such appliances on the London streets?

Electric Lighting in Italy.—Work has been commenced in connection with the electric lighting of Battaglia, Venetia.—A company is being formed at Biella to acquire the powerful Cana Vesano waterfalls, 18 miles distant from Biella. About 600 h.p. is available.—At Campobasso the electric light is to take the place of petroleum lighting.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

HIGH-INSULATION RESISTANCE.

SIR,—The following insulation tests may be of interest to you, seeing that the system adopted at Blackburn is the same as that at Nelson, put down by me in 1893, and which has proved so free from faults—viz., a three-wire system, consisting of cables continuously insulated with vulcanised rubber and supported upon vitrified stoneware bridges, and fixed within a cast-iron conduit kept water-tight by means of steel junction-pieces.

The following test of feeders and ring main and pilot wires took place at Blackburn in the presence of Mr. David McDowall Grosart, M.I.E.E., the consulting engineer to the Corporation of Blackburn, and Mr. T. L. Horne, A.M.I.E.E., representing Messrs. Siemens Bros. and Co., London.

The total length of cable laid is 6·75 miles. The insulation resistance, including pilot wires, is 190 megohms.

The test of the separate cables are as follows, after two minutes' electrification:

+	1,620 megohms per statute mile.
Middle,	1,530 megohms per statute mile.
−	1,580 megohms per statute mile.

The specification issued by me was for 800 megohms per statute mile. This result is therefore highly satisfactory, being nearly double the guarantee. The cables are of Messrs. Siemens Bros.' manufacture.—Yours, etc.,

THOMAS BARTON.

The Electric Works, Blackburn, January 15, 1895.

DIVIDED POLE-PIECES.

SIR,—I note in the description of the new dynamo which Messrs. Thomas Parker, Limited, have just introduced, that one of the novel features in it is the splitting of the magnet pole so that the armature can be readily taken out. I do not know whether this would have been considered a novelty about six years ago; if so, I am entitled to claim it, as I fitted all the two-pole dynamos which my firm have made for the past six years with the magnets split in the same way as Mr. Parker's machine. I have found it extremely convenient, as it enables the armature to be very readily removed if required.

At the same time, I did not consider it worth bringing very prominently forward at the time I designed and built the first two-pole machine, and I am quite sure that Mr. Parker, with the desire for fairness which I know he possesses, has not made this claim with any knowledge of what has been previously done.—Yours, etc.,

M. MOUNTAIN.

Newcastle-upon-Tyne, January 15, 1895.

UNDERGROUND CONDUITS.

SIR,—Having had considerable experience in the construction of underground mains, I am of the opinion that the best way to prevent these explosions is to properly drain and ventilate culverts and boxes. There is not much doubt but that these points have been neglected, or have not received the consideration deserved, at the time of the construction of some of the mains both in London and the provinces. I know that to lay tubes and culverts with proper falls to junction, etc., boxes, adds considerably to the difficulty in laying, owing to the many obstructions met with underground, and unless a very sharp eye is kept on the workmen the levels will very soon be neglected. At the lowest points, which must be at a junction or service box, it is a simple matter to construct a "sump" or "catch-pit," from which any water can be drawn at certain times. I am in favour of this system in preference to connecting to the sewers, as I have found that almost every form of "trapping" is likely at some time or other to fail, in which case sewer gas would be carried all through the district and into the houses of those using the current, with most disastrous effects. It was on this account that

Digitized by Google

I abandoned a design which I worked out over four years ago. In districts near the sea or rivers there is also the danger of back-water from the sewers at times of high water or floods through any slight defects in the traps.

As regards ventilation, I would allow coal gas or any other gas to wander about as it liked underground, for although it may not be altogether impossible to keep it out of culverts, boxes, etc., it would be a most expensive business to attempt properly, as gas very soon finds its way through concrete or brickwork. Clamping caps over the ends of pipes, either spares or those carrying cables, would not protect the boxes themselves; besides, there would always be the risk of their being left off by the workmen. Dried air forced through the entire system of conduits and pipes is a splendid means of ventilating—in theory, but I have grave doubts as to its entire and complete success in practice, especially in the case of a large district or town where the network is connected up at many different points. There would, it seems to me, be certain portions of the mains—those farthest to reach or where culverts or pipes were of a smaller size—that would never reap any benefit; besides, there is the cost to be considered.

In the construction of new mains, it is, of course, much easier to make arrangements for both drainage and ventilating, and there is not much doubt but that in the future these questions will receive more consideration than they have in the past; but the matter which should be considered immediately is how to deal with those mains already in use. The different systems would probably be better dealt with separately and on their individual merits. What might be suitable to conduits may require modification for pipe mains, etc.

Putting the question of cost on one side, the business would be much easier dealt with, but, unfortunately, the cost must be considered, and with this in mind a system adaptable, with slight modifications, to the various kinds of mains in use would be to connect certain manholes or boxes (in the case of cable and pipe mains all junction boxes, and where these are too far apart some of the service boxes; in culverts, at all junction-boxes, and where these exceed about 50 yards, the service boxes at about this distance, and always at the end of a culvert) by means of an earthenware drain-pipe to a box (an ordinary gully trap will do), with a cast-iron lid in which holes of a combined area exceeding that of the drain-pipe are cast, each with a ridge round to prevent water running in. This box or trap should be fixed at a higher level than the manhole or service box, and as close as possible to a wall or building; it will then be sheltered from rain, dirt, and traffic. I have seen these successfully in use, and requiring very little attention.

There are, of course, other ways which might be better than these that I have mentioned, but I think for cost they will give good and satisfactory results.

For the sake of electric lighting, and to prevent further injury and mischief being done, this matter should be taken in hand at once.—Yours, etc.,

B. H. JENKINSON, A.M.I.C.E.

13, Mildenhall-road, N.E., January 16, 1895.

REVIEWS.

Proceedings of the International Electrical Congress held at Chicago, August, 1893. Published by the American Institute of Electrical Engineers, New York.

Probably those who attended the congress at Chicago 18 months ago carried away with them enough reminiscences to render any tangible reminder unnecessary, whilst the vast mass of electrical men who didn't go have retained only a memory of reports in the technical Press, dealing with attempts at unity in units, or comprising acres of pages on alternating-current theories, with here and there a few eminently practical results worth laying hold of for daily use. It is possible that *some* may have forgotten all about the congress and its objects, and to such the chance is now afforded of parting with their dollars to refresh their memories as to what was done, or—still more important—what was attempted. In a volume of some 500 pages, we have here a complete record of the entire congress—papers, discussions, etc.—accompanied by a photograph of the official delegates. Better late than never, it may be thought; though the publication of this report has been so long deferred that death has already claimed a foremost figure from the group depicted. No longer, alas! will Von Helmholtz be called to assist in work of this kind. That the rest are still amongst us is a matter for congratulation, and yet more so if they endure until the next congress, now not very far remote.

THE MAYORALTY OF TUNBRIDGE WELLS.

SIR DAVID SALOMONS'S BANQUET.

Reaching Charing Cross Station some five minutes before the train started on Saturday, I wondered what sort of a run down we should have. It was bitterly cold, with a piercing wind, and not even the attraction of the saloon carriages attached to the train was sufficient to prevent my becoming ensconced in the corner of a private smoking compartment. I had been invited to be present at the banquet given on Saturday by Sir David Salomons, Bart., to celebrate his election to the mayoralty of Tunbridge Wells.

My fellow-passengers were newspaper men—a jolly set they were. When we arrived at Cannon-street, the Lord Mayor (Sir Joseph Renals) and friends entered the train, which then resumed its uninterrupted course to our destination. Of the happenings during the journey there is little to say.

The representative of one paper, a red-faced man, wanted to know why Sir David was giving the banquet. Another thought it was to get an advertisement. I ventured to suggest that Sir David, being so well known, had no occasion to advertise himself, and that he would not attempt to do so. "Do you see this?" asked my *vis-a-vis*, handing me his card of arrangements for guests from London, "'Vehicles will be in attendance, should any gentlemen wish to avail themselves of these to convey them across the road to the hall.' Rare fun, is it not," he added, "vehicles to convey visitors across the road; why, it's only 30 yards."

No one seemed sorry when we reached Tunbridge Wells, where a guard of honour awaited us—I mean the Lord Mayor. It was still terribly cold, but this did not prevent all Tunbridge Wells from turning out to witness the arrival of the company. The members of the local volunteer corps, assisted by the fire brigade, kept order—and the cold.

Passing into the ante-room, Sir David, attired in his robes of office, and assisted by the Corporation, most graciously received us. I was unable to secure the plan of the tables allotted to me, and had to be content with that of Mr. C. Semark, who can have it on application to this office.

The dining-hall was very effectively decorated. At one end, where the principal guests sat, was a raised platform, on the front of which was a bank of ferns and other foliage plants; at the other end was another platform, where a portion of the Royal Engineers' band rendered a musical programme during the evening.

A glance round the hall showed many familiar figures in the scientific and legal world. Besides the Lord Mayor, the company entertained by Sir David included the Marquis of Abergavenny, Viscount Cantelupe, Lord George Nevill, Lord Sherborne, Mr. Justice Grantham, Sir Julian Goldsmid, M.P., Sir Frederick Abel, F.R.S., Sir W. G. Stirling, Sir George Russell, M.P., Sir Frederick Bramwell, F.R.S., the Astronomer-Royal (Mr. W. H. M. Christie, F.R.S.), Mr. Alderman and Sheriff Samuel, Mr. Sheriff Hand, Sir B. W. Richardson, Sir James Crichton-Browne, F.R.S., Prof. Hughes, F.R.S., Mr. Bousfield, Q.C., M.P., Mr. Alderman Faudel Phillips, Sir Henry Knight, Mr. A. G. Boscawen, M.P., Sir H. C. Mance, Prof. Ayrton, F.R.S., the Master of the Skinners' Company, the Master of the Coopers' Company, Mr. Macrory, Q.C., Sir J. Winfield Bouser, Mr. D. Fearon, and the mayors of Brighton,

Digitized by Google

Eastbourne, Lewes, Folkestone, Hastings, and Maidstone, Mr. F. Webb, and others. Lord Kelvin was not present, and I was unable to find Mr. W. H. Preece, the consulting engineer to the Corporation.

The entrance of Sir David was heralded by two trumpeters, whose blasts seemed to somewhat vex the mayor. The ceremony resembled some mediæval function, and reminded me very forcibly of the external proceedings at the advent of judges years ago at the entrance to courts of assize. At the conclusion of the dinner, the toast list, which I give below, was proceeded with.

The toast list is, however, not sufficiently detailed. It does not mention that given by Mr. F. W. Stone—"Sir David Salomons"—to which Sir David suitably replied.

The Mayor—"The Queen"...	
The Mayor—"The Prince and Princess of Wales and Rest of the Royal Family"	
Sir George Russell, Bart, M.P.—"The Navy, Army, and Reserve Forces"...	Capt. Stiffe, late E.I.N. General Light, R A., ret. Colonel Sir George Stirling, Bart.
Sir J. Crichton Browne, F.R.S.—"The Houses of Parliament"	The Marquis of Abergavenny, K.G. Sir Julian Goldsmid, Bart., M P.
Lieut.-Colonel A. M. Brookfield, M.P.—"Bench and Bar"	Mr. Justice Grantham. Mr. Bousfield, Q C., M P.
The Mayor—"The Corporation of the City of London"...	The Lord Mayor. Mr. Alderman and Sheriff Samuel.
Mr. A. G. Boscawen, M.P.—"Neighbouring Corporations"	The Mayor of Brighton.
The Lord Mayor—"The Corporation of Tunbridge Wells"...	The Mayor.
The Mayor—"The Guests"..	The Astronomer Royal (Mr. Christie) Sir Benjamin Ward Richardson, M.D., F.R.S. Mr. W. F. Browell

Evidently Mr. JUSTICE GRANTHAM is a ready wit. In responding for "The Bench," he said that "the Mayor of Tunbridge Wells has given us a dinner. Without any desire to disparage his worship's hospitality, I think I can do better than that. I can give you not only food, but lodgings. I can give any number of men free board and lodging, with an extra present in the shape of six months' hard labour." Now, I think this is a little too bad. At any rate, I hope this statement was not the cause of the sudden disappearance of several of the guests.

Sir DAVID SALOMONS, in proposing the "Corporation of the City of London," mentioned the interesting fact that his uncle had once occupied the position of chief magistrate of the City, and referred to his connection with the electric lighting of the main thoroughfares of the City of London. Continuing, he observed that there were men who thought that institutions which had grown through centuries could be swept away in a day. That could not and would not be done. Many people imagined that Sir J. Renals would be the last Lord Mayor of the City. His own belief was that there would be many more Lord Mayors, and that among them would be his guests, Mr. Alderman Phillips and Mr. Sheriff Samuel.

The LORD MAYOR, in acknowledging the toast, remarked that the first of his Jewish predecessors as chief magistrate was the chairman's uncle, who did much for the cause of civil and religious freedom in this country. At present, his lordship went on to say, they were engaged in defending the privileges and prestige of the Corporation, which, although it had existed many centuries, was still young and vigorous. Whoever had the honour to respond to that toast in years to come, his lordship continued, would be able to declare, as he did then, that the Corporation of the City of London was still pre-eminent for the hard and enduring work and the generous and impartial charity which had distinguished it in the past.

In the course of another toast it was mentioned that in another month Tunbridge Wells would have available a municipal supply of the electric light.

Shortly after 11 many of the guests returned to town. The train stopped two or three times to set down visitors, and reached Charing Cross at 12.55, where the guests were welcomed by snow and cabs.

TRANSFORMER-CHAMBERS IN LONDON.

BOARD OF TRADE DECISION.

We give below a copy of the letter which has been addressed by the Board of Trade to the London County Council and other local authorities in the Metropolis. The decision in this matter concerns the House-to-House Electric Light Supply Order, 1889; the Hampstead Electric Lighting Order, 1892; County of London (North) Electric Lighting Order, 1892; Southwark Electric Lighting Order, 1892; Wandsworth Electric Lighting Order, 1892; and the Islington Electric Lighting Order, 1893. The letter is signed by Sir Courtenay Boyle.

"With reference to the hearing which recently took place at this office of objections raised to the various systems of supply proposed to be adopted by the undertakers under the above-mentioned orders, which involve the use of transforming-chambers placed underground in the public streets, I am directed by the Board of Trade to inform you that, as arranged at the hearing, they have consulted their legal adviser, who is of opinion that the expression, 'regulating or controlling the supply of energy,' means or includes the transforming of energy, and accordingly that there is sufficient authority in Section 12 of the County of London (North) Electric Lighting Order, 1892, and in the corresponding sections of the other orders mentioned above, for the construction of such boxes as may be necessary for that purpose; and, further, that, so far as the section itself is concerned, there is no limitation with respect to the size of the boxes.

"In view of this opinion, and after a careful consideration of the representations made at the hearing, the Board of Trade are not prepared to hold that sufficient reasons have been advanced, either on the ground of public safety or of want of parliamentary sanction, to justify them in refusing to approve of a system of supply which involves the use of transforming-chambers under the public streets. The Board of Trade, however, consider that the user of the public streets for such a purpose should be as much as possible limited, and that the chambers should be placed where they do not unreasonably interfere with existing underground works of any kind. In these circumstances the Board of Trade will be prepared to approve the systems submitted by the undertakers under the above-mentioned orders with certain alterations, which will be communicated to the Council shortly.

"The Board of Trade hope that their decision on the general question will render unnecessary any further action with regard to the appeals which have been lodged by the undertakers under Section 13 of the County of London (North) Electric Lighting Order, 1892, and of the Wandsworth Electric Lighting Order, 1893. Should, however, any difficulty arise in connection with any particular chamber, it would, of course, be open to the London County Council, the local authority, and the undertakers to avail themselves of the provisions of the sections of the orders relating to the construction of works."

NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

Presidential Address Delivered January 14 by Mr. Henry Edmunds.

I feel a peculiar responsibility in addressing you this evening, and it is at some personal inconvenience to myself that I have come down here to-day from London, where I have to return early to-morrow. It was kindly suggested by some of the members that I might write my address and it should be read for me, but I felt it would be better to speak face to face, especially when I remembered that this was the first presidential address. Now, if we are serious and want this society to take a lasting and dignified position in the country, it is well for us to carefully consider the objects and future of the society, and see what each individual member can do to further the interests of the Northern Society of Electrical Engineers as a whole, rather than consider his personal convenience, business interests, and self-advancement. In some quarters the question is asked: "What need is there for such a society as ours? Have we not already the Institution of

Digitized by Google

Electrical Engineers and other kindred societies?" The answer may be considered chiefly geographically. It is difficult for men living in the North to attend regularly the meetings held in London, and the mere reading of the proceedings of the London meeting does not compensate for the absence of personal contact and debate. This society is not an offshoot nor an affiliated member of the Institution of Electrical Engineers, but an independent body, though composed of men having kindred interests and tastes, many of whom, like myself, happen to be members of both the Institution of Electrical Engineers and the Northern Society of Electrical Engineers. Therefore, as an independent body, we must carefully consider what our aims, interests, and objects are, and see if they differ in any way from those of other institutions. If our objects are exactly alike, we may be said to be in competition; and if in competition, we must naturally try to excel and do better than those we compete with. I think a little competition among societies may be as healthy as in commerce. Now, we are a formed society, one year old; we have 125 members, a balance at the bank, and are financially sound. Our society is respected so far as it is known by kindred societies, and its papers and discussions have been published and commented upon by the technical journals, and now at its first birthday it may be said to have justified its existence. But what is its future going to be? That brings me to the most serious and important part of this the first presidential address. If we wish to live, grow, and be respected, each member must contribute his own individual effort. Each one must feel himself honoured by being elected a member of this society, rather than consider that he confers an honour to the society by joining it. I speak in this way as I fear that at some of the meetings during the past year this idea may have been overlooked. It is probably excusable when we consider the youth and consequent inexperience of the society, but as we grow older we must grow wiser and stronger—we must consider what the aims and objects of this Northern Society of Electrical Engineers should be. We may divide these objects into (1) the practical and technical; and (2) the social.

I put practical first, because in looking around me I see so many men who are interested rather in the everyday work of constructive electrical engineering than in the pursuit of scientific research. We may further divide our engineers into two classes—consulting and constructive. A word to the consulting engineer may be well brought in here. In the first place, the profession is an important and useful one. It is the duty of the consulting engineer to plan out, design, and to guide those who have no technical knowledge of their own. Corporations and individuals employ the electrical engineer in the same manner as they employ their architect, their gas or water engineer. But our profession is a young one. During my connection with it, which dates back from 1877, I have seen the gradual falling into rank of men who in 1877 were unheard of and unknown. The electrical engineer of that day was essentially a telegraph engineer, and his ideas, with few exceptions, were limited to the working of land or submarine telegraphy. I often think that the rapid advance of electrical engineering was retarded in consequence of the limitations to the mechanical and engineering side of the question, which limitations were set by men whose knowledge was mostly confined to magnets covered with fine silk-covered wire, and currents that could not vibrate the indicating needle of a modern central-station ammeter at zero. I would not for one moment reflect on the gentlemen of 1877, but only wish to indicate to you that the electrical engineer is a creation made since then. He has had a very long childhood, and, like the rest of us, has had a great deal to learn and unlearn. Naturally, when work was placed in the hands of the new engineer, when he became consulting rather than constructive, he was apt to please his vanity and try to justify his existence by changing every dimension and detail he possibly could in existing machinery and appliances. And it did not end with merely painting the machine another colour; but each engineer varied the speed of his dynamo, the pressure of his mains, the type of engine which should drive, and the thousand and one details which, while they might not interfere with the result of the whole, have had a very serious interference with the advance of the electrical industry. In England, I think, we have been as much cursed with amateurish engineers as they have been blessed in America with the absence of them. I recollect very well when I first met Mr. Brush in Cleveland, U.S.A., in 1879, and saw his very plain, but useful, arc lamp, I thought it might be considerably improved, and told him so. He looked at me, and said, "It works! What we have to do is to sell them." And they did sell. I was instrumental in the introduction of that system into England. Many people came to see our first installation in Hatton-garden, and then at the Liverpool-street railway station, and nearly everybody said how much prettier they might make the arc lamp. Engineers and others who were asked to tender for building the Brush plant and apparatus in nearly every case had some suggestion to make for the alteration of dimension and detail, in order to suit each individual whim. The result was that we were much longer in making progress in England in the introduction of the arc light than they were in America, though I do not wish to infer that this was wholly attributable to this cause, yet it was to this, among others.

Now, what we want in a consulting engineer is a man who can recognise first what is best in the market, best for actual merit, and most suitable for his requirements—a man who can guide those whom he advises in their selection of the best thing for the work to be done, and who will be content to leave matters of constructive detail in the hands of honest manufacturers whose interest and profit shall lie in making a good thing, rather than producing some type or variation of design of which he practically makes only one—and that an unsatisfactory one—instead of many which can grow each in quality through experience in manufacture, and where there is a margin of profit, which in many manufacturing operations is larger in consequence of numbers and output. My remarks refer of course to the immature engineer, and naturally can have no reference to individuals present. Our consulting engineer can be of great help to us if he works conscientiously. He will see that what is undertaken by the contractor is carried out efficiently and well; and I also think it is his duty to see that not only do those who employ him get good value for their money, but also that those he employs get a reasonable margin of profit on their work. This brings me to another and very important point. We find all around us towns, corporations, and companies that are going in for the public supply of electricity. We find a huge new industry in which thousands of pounds of capital are invested. Many of the most advanced minds are at work in developing mechanical and electrical details, and yet we find that, with very few exceptions, nearly every manufacturer who tenders competitively for work says he will be practically without profit if he gets the contract. Now, something is wrong in this. I admit that competition (which, after all, cannot be prevented) has a great deal to answer for, but I think, on the other hand, that many of our consulting engineer friends (and, as I said just now, it is their business to see, they being disinterested themselves) should see that both parties to the bargain, those who buy and those who sell, are taken reasonable care of. It is a curious fact that there are large corporations around us that have plenty of money (that they can borrow at a low rate of interest) buying electrical machinery and plant that barely pays a profit to anyone concerned. And yet these same corporations, acting under the advice of their engineers, would be perfectly willing to pay a fair price. In many cases I have known that engineers' estimates are allowed that would have given a reasonable working profit to all the contractors and undertakers, but these were undercut by the competing firms. I merely mention this here in connection with our consulting friends, who, I am sure, can be of great assistance to us. But the fault is not theirs.

Now, we will pass from the consulting to the constructive engineer. In this class we include both manufacturers and installers, and we may consider these gentlemen from both an electrical and mechanical standpoint. In electrical engineering of to-day—I mean where we are converting heat energy into electrical energy through the medium of dynamos and generators—the mechanical engineer plays an important part, and I am glad to see that the society has among its members many gentlemen who may be said to belong exclusively to the mechanical side. They must, however, in order to justify their membership of a society of electrical engineers, see how closely the union between the electrical and mechanical is growing. It must not be sufficient for them to say that they make an engine that can run at a given speed, and that such engines as they have built have been working in connection with Lancashire boilers in our cotton and other industries here for the last 25 or 30 years. I do not suggest that many engineers say this to-day, but I remember in the early days of electric lighting the man who made a small portable agricultural engine said he had got everything that was required for our purpose, and I remember what difficulties we had in getting these people to see that the requirements of a mechanically-driven dynamo were different from that of driving a thrashing machine. To this engineer, they both went round, and I remember that a man would say that his engine could do such and such work, and could certainly drive that bit of a thing—the dynamo. He would come and watch his engine—the stoker perspiring, the water running down, and the steam running down still quicker—and he would stand and wonder where on earth the power was going to. We have left these days, however, and the mechanical engineer is awaking to the fact that perhaps the biggest field he will have in the future will be in connection with electricity. In a district like this, where thousands of engines are used daily for driving mills, with their miles of shafting and belting, manufacturers are beginning to wonder why they should use such huge engines at times when their loads are light and only part of their works are running, and they have to lose so much in unnecessary shafting and belting, friction, etc. In many places I am glad to say that, following the electric light plant, has come

Digitized by Google

the electrical distribution of power plant. Electric motors are taking the place of shafting and wires the place of belting, and I advise our engineer friends to look well to this outlet for their industry during the coming period.

Now, for our electrical, as apart from our mechanical, engineers—the men who by their thought and work have designed our alternate-current dynamos, our continuous-current machines, our multiphase machines, our transformers, our arc and incandescent lamps, our measuring instruments, and the multitudinous accessories. These men must try to get as far as they can from the traditional millinery of the philosophical instrument maker, and must see that they must combine with their electrical requirements the very best mechanical conditions and surroundings. They must also work hand-in-hand with the mechanic. They must get away, as they are doing, from the sealing-wax and brass lacquer, and they must remember that in work of the magnitude that is likely to come on durability is going to play as important a part as efficiency, and they must not sacrifice to efficiency the many other requirements of practical everyday use. I have not intentionally spoken slightingly of our friends the telegraph engineers. Some of my references have only been to those earlier and respected men whose knowledge was necessarily limited to the electrical portion of their work, so that they did not appreciate the conditions of the mechanical portion. I am glad to say that we have among the members of our society those who are interested in telegraphy and telephony. Telegraphy, more especially as relates to submarine work, could be effectively dealt with by one who I regret to see is not here to-night—I mean our respected member, and one of our founders, Mr. George Preece; but that being a branch in which the assembled members take little interest, I will not refer further to it. Telegraphy, I may say, seems to be a completed and perfected branch, which may probably continue to grow in bulk, but which will more probably be more or less supplanted by telephony, which has made giant strides during the last few years. Among telephone engineers large and important problems have to be worked out. An ever-increasing number of subscribers means an ever-increasing difficulty in wayleaves and communications. I have no doubt that we shall receive in the future interesting papers from gentlemen connected with this branch, and they will be able to point out to us how they have overcome both their mechanical and electrical difficulties. They will watch with jealousy the introduction of those large power systems for fear of interference by induction and other causes, and engineers will do well to consider here in concert with one another how they can each give and take, how they can each learn something of the conditions and requirements of the other without experiencing either annoyance to themselves or interference with public requirements.

Our telephone engineers must not think that they "own the earth" because they happen to have been born first; nor must our electric traction friends think that because they wish to come in as well they can ruthlessly remove all existing systems. There has been during the last few months an animated discussion with regard to these matters, and if the discussion necessary for the removal of these difficulties can be carried on here by papers and debate, I have no doubt that those will be among the things that will justify the existence of this society. We shall have in the near future an enormous advance in connection with electric traction. In 1883 I was interested in being asked by the Blackpool Winter Gardens Company if I could run a small electrical carriage. I placed this in the hands of my friend Mr. Holroyd Smith, of Halifax, who afterwards constructed the Blackpool electric tramway; and it is interesting to see that since that date till practically within the last 12 months there has been comparatively no advance in this country in connection with electric traction. On the other hand, in 1885 I was in America, and was there interested in the pioneer company—the Bentley-Knight. I went out to Cleveland to see the experiments in electric traction, and since then (1885) to the present moment (January, 1895) there has been such an advance that there are now 9,000 miles of electric tramway track, as against 4,000 miles of horse tramways; 20,000 electric cars are run, and hundreds of thousands of horse-power are employed in driving the electric plant. And the capital invested amounts to 225,000,000dol. (£45,000,000). Now, one reason, among others, why we have been held back so much has been the miserable petty jealousies among our own engineers, among men who ought to know better, who would rather that the work of construction should go to America than that it should be done by an old competitor and countryman. Of course in these remarks I have no reference to the members of the Northern Society of Electrical Engineers, for fortunately they have not lived long enough to have a history of this kind. I wish this society to avoid these petty jealousies. On several occasions on which I have had the honour to address you I have referred to questions of this kind.

And this brings me now to my installing engineer. It is somewhat difficult to define an installing engineer or contractor. I believe that every man who can use a piece of cotton-covered wire, a pair of pliers, and a soldering iron, describes himself as an electrical engineer. We do not want to give limitations to the aspirations of the man who begins at the bottom of the ladder with his wire and pliers, but we do want to give limitations that will secure reasonable productive profits to a business that ought to be carried on well, and not subject to the ceaseless and unnecessary cutting competition that we experience. In our installing engineers we ought to have men who have the interests of their work at heart. They have to go into buildings and instal their system of wires and cables, making them as little obtrusive as possible, and to take care that there is the least interference with the carrying out of the ordinary work that is being done in those buildings. Now they have to do, or ought to do, honest work, but I have unfortunately seen many cases in which a competent firm has determined to go for a job and get it at any price, and has then endeavoured to do as little as possible in order to try and do the work at somewhere near the contract price. In the old days we used to get 40s. a light, or point. I do not say that this was not too high, but when we come down to 7s. 6d. a point, either the people in the old time made an outrageous profit or the people in the present time do work that cannot be justified. There is, I am afraid, a tendency for a great deal of "eye service" in this. As long as the switches will turn on the current to the lamps, and no questions be asked as to the condition of affairs between the dynamo and the lamp, or the wires, joints, and cut-outs, some people are satisfied, always provided they can get their bills paid. But, after all, this is a very short-lived policy. We must not bring our business into disrepute by cheap and ineffective work. I recollect in America that a manufacturer of cotton goods told me that he had had a large enquiry and was doing a considerable business in China, and that he believed some of his cottons were being imitated and sold under a similar mark by Manchester houses, which, while he considered it very flattering, was a great surprise to him till he looked into it. I myself looked into the question, and found that in this district of Manchester there had been a practice of dressing or loading cottons with certain mineral substances and earths in order to give an attractive finish and heavy weight, and which could be sold to the unsuspecting foreigner at a much greater profit in close competition, because it was naturally considerably cheaper to load with earth than with cotton. These goods were sent out to China, and poor John Chinaman and his friends discoyered that the first shower of rain, instead of glancing harmlessly off his clothes, washed away all the earth in his cotton suit, and left him practically enveloped in a sieve. The Chinese then found that the practice of loading cotton had not then been extended to America, in spite of the proverbial "'cuteness" of the Yankee, because, owing to his protective tariffs and other conditions, the American manufacturer was able to make a reasonably good article and sell at a comfortable price, and although they commanded a higher value in China they were preferred to the English article. Thus the Manchester goods got a bad name difficult to recover, and the American got in as maintaining his quality. Now, I am not addressing you as generally being in the Manchester trade, but as we happen to live and work in this district, let us be warned by the mistakes of others and take care not to commit them ourselves.

Now, then, to you contractors. See that your work is well done. See that your work can pass muster by our friend the consulting engineer, and by our esteemed friend Mr. Heaphy and other representatives of the fire insurance offices! If you do your work honestly and well, you will find that it will pay you. You will be able to say that for work bearing the reputation of your name you must have a certain price, and let the men who want to cut, cut, and do as bad work as they please. They will soon either go right out of the trade or find it is useless to do bad work for nothing. They will see the folly of their ways, and do better work at a profit. It must not be left (as is unfortunately too often the case) to contractors to say, "Well, we do not mind what we get for the work as long as we can vary the tender. We can then make our profit on the extras." This, gentlemen, to my mind is not right.

Now, I have gone carefully over the different interests of the society. I have tried to call your attention to our individual selves, and now I want to look at ourselves collectively. As we have seen, we have grown during our first year rapidly and satisfactorily. But it is not sufficient that we should grow simply in numbers. I said that, in addition to the practical and technical objects of our society, we had another one, the social element to consider. If this body poses as a purely scientific society, which it evidently does not, we might, in the regions of pure science, almost feel that we could ignore social considerations. But as the bulk of our members are eminently practical, our social relations to each other become important; and it is here I think that this society has a large field for usefulness, and I should say that the introduction of dinners, smoking concerts, excursions, and other social gatherings, if judiciously carried out, may be found to be a most useful thing for us all. When men in similar pursuits only meet each other from a business point of view, they are apt

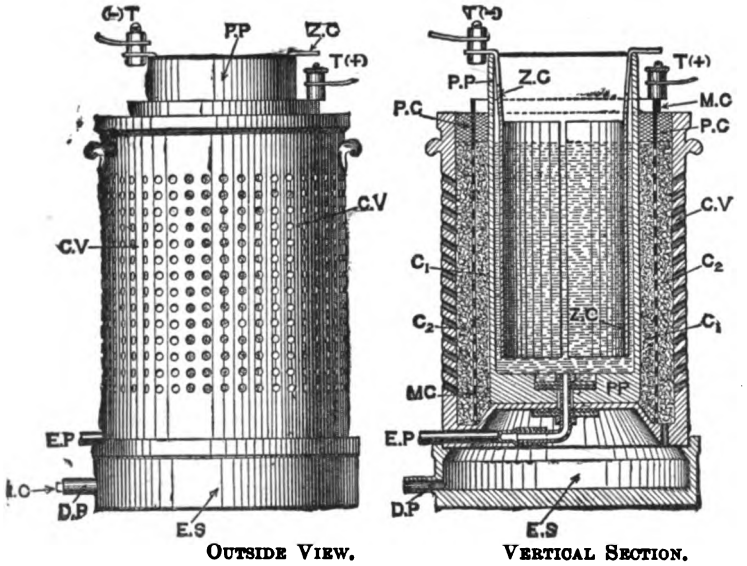
Digitized by Google

to see each other to the worst advantage. I am glad to say that men whom I once did not care to meet because our interests were conflicting have on further acquaintance been those I honoured and respected most. You will probably find this to be the case here; and if, instead of the manifold petty jealousies that are apt to be fostered among members of the same profession, you will get into an inner or family circle, recognising that you are members of the same family and have an equal right to live and let live, and that by good feelings of brotherhood and give-and-take, and not each one going for himself, you may be able to do a vast amount of good in the future. How often would it be useful for men to honestly and honourably get together to discuss certain points and questions of prices, policy, and quality of work, rather than only know the price when tenders come out and the quality when the work is done. It is not as though there were not enough work for all. The extension of the electrical industry is practically unlimited. Lighting, traction, telephony are yet, comparatively speaking, in their infancy. And when we come to such things as electrical transmission of power, electro-deposition, electro-chemistry, electric welding, heating, cooking, and smelting, we can see the field that can be practically and profitably occupied by everyone connected with this industry. But in order to occupy this field well we must have a proper recognition of the rights of each other, and I trust that you will receive the remarks that I have made in this address and apply them practically to yourselves. I trust that you will not consider that I have taken advantage of my position as president to give an address which is not to be discussed, and which may appear to be rather in the nature of a homily than of a technical discourse. The scientific and technical discourses must come along in the future. My only wish is to endeavour to lay a proper foundation on which the structure can be built, and I wish it to be that in 10 years time, when you hear your then president address you, that those there present may look back with feelings of gratitude and pride to the time when they first became members of the Northern Society of Electrical Engineers.

THE "WALKER-WILKINS" NON-POLARISING BATTERY.

We have received for publication the following report by Prof. Andrew Jamieson, M.I.C.E., F.R.S.E, on the above battery:

Having received from you specimens of your non-polarising cells, with a request to test and report upon the same, I have much pleasure in stating that I consider them symmetrical in form, substantial in every detail, and thoroughly well made; besides which they have proved very efficient (chemical) generators of electrical energy. As will be seen from the following drawing and index to parts, your cell is composed of an amalgamated split

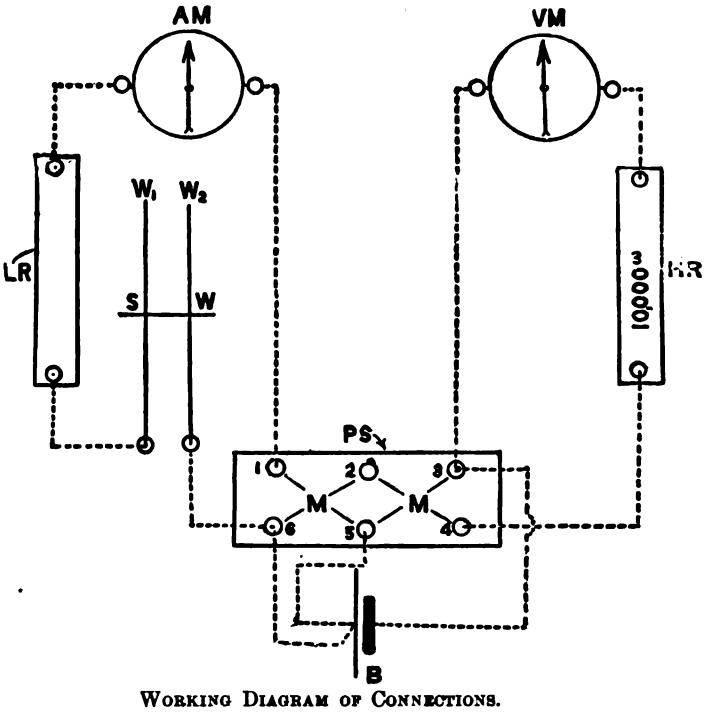


OUTSIDE VIEW. VERTICAL SECTION.

Index to Parts.—T (-), negative terminal; Z C, zinc cylinder; P P, porous pot; P C, pitch covering; C_1, carbon (powdered); C_2, carbon (granular); M C, metal cylinder; T (+), positive terminal; C V, containing vessel; E P, emptying pipe; D P, drain pipe; I C, indiarubber corks; E S, earthenware stand.

cylinder of zinc immersed in a solution of caustic potash, contained in a porous pot, placed concentrically within a larger perforated outer vessel. The space between these vessels is packed with carbon, the carbon in contact with the porous pot being powdered, while that next the outer vessel is granular. The current is collected by means of a perforated nickel cylinder embedded in the granular carbon.

Advantages.—The advantages which you claim for this cell are (1) freedom from offensive or obnoxious fumes when working; (2) the simplicity of the cells and of the charging solution; (3) the almost entire absence of local action, and unnecessary waste of zinc. I am glad to be able to corroborate these three claims. You also say that the cells have been introduced to meet the long-felt want of a reliable primary cell which does not polarise, and which keeps a constant current up to a certain rate of output. The following tests and curves will enable anyone who understands this important subject to judge how far your aims have been accomplished. The following diagram shows the arrangement of the testing connections:



WORKING DIAGRAM OF CONNECTIONS.

Index to Parts.—B, battery or cell under test; P S, paraffin switch; M M, mercury contacts; A M, ammeter; V M, voltmeter; H R high resistance (10,000 ω); L R, low resistance; S W, slide wire; W_1 W_2, wires for variable slide resistance.

TABLE I.—WEIGHTS AND DIMENSIONS.

Two-pint size.	Weight charged.	Dimensions.
No. 1	19lb. 3oz.	Total height.
No 2	19lb. 5oz.	Including stand.
No. 3	19lb. 1oz.	14in. × 8¼in. diameter

THE TESTS.

(1) *Potential Current—i.e.*, the variation of the potential difference at the terminals of each cell due to the variation of the current strength in its external circuit.

(2) *Total Output in Ampere-Hours—i.e.*, the cell was allowed to discharge through a resistance so varied as to keep the current constant.

(3) *Recuperativity—i.e.*, the rise of E.M.F. after being short-circuited through a copper voltameter for two days. The output in ampere-hours being measured by the weight of copper deposited in the voltameter.

(4) *Internal Resistance* as calculated from the results of Test 1 given in Tables II. and III.

Two galvanometers were used, as shown in the preceding diagram of connections, one of very high resistance as a voltmeter, and the other of very low resistance as an ammeter. The high-resistance galvanometer was so controlled as to give a deflection of one scale division for 0·0044 volt. A "Latimer Clark's standard cell" (of 1·454 volts at 15deg. C.) produced a deflection of 330 scale divisions. Consequently, one scale division $= 1 \cdot \frac{4}{330} = 0044$ volt. The low-resistance galvanometer was under strong magnetic control, and shunted by a short thick copper wire. It was then carefully calibrated to read in milliamperes.

TABLE II.—POTENTIAL CURRENT TESTS. (For Cell No. 1.)

Current in amperes.	P.D. in volts.	E M.F. at end of each five minutes.

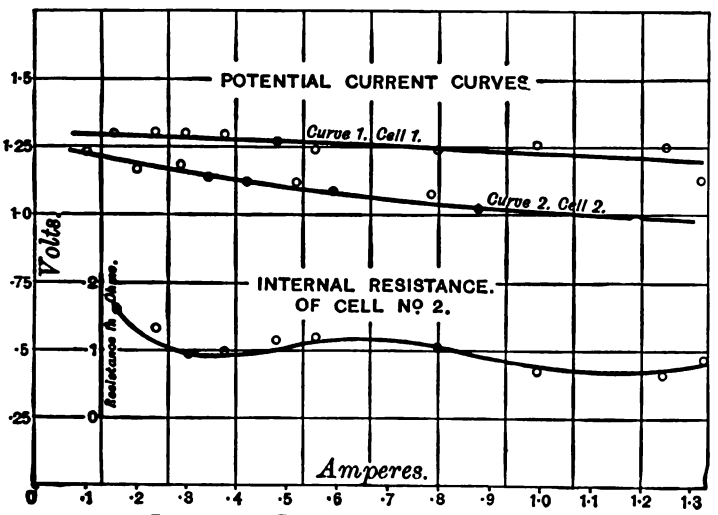
The preceding table shows the results of test No. 1, or that of the potential current test. The cell was joined up as in the preceding diagram, and its E.M.F. measured. A current of a certain value was then obtained from it for each period of five minutes. At the end of each such period the potential difference and current were simultaneously noted. The external variable resistances (L R and W_1 W_2) were then reduced, so that the current was increased until it had risen from 0·156 ampere at the beginning to 1·346 at the end of the tests. Eleven readings were thus obtained from cell No. 1.

The same test again was made with another cell—viz., No. 2.

TABLE III.—POTENTIAL CURRENT TESTS. (For Cell No. 2.)

Current in ampere.	P.D. in volts.	E.M.F. at end of each five minutes.
·000	—	1·371
·100	1·229	1·244
·205	1·180	1 227
·290	1·152	1·207
·348	1·137	1 196
·422	1·123	1·185
·520	1·105	1·182
·590	1·087	1·176
·783	1·052	1·170
·870	1·023	1·164

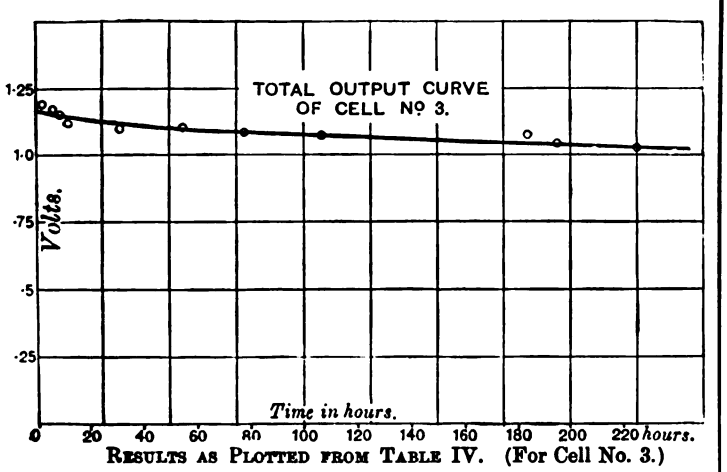


RESULTS AS PLOTTED FROM TABLES II. AND III.

TEST II.

TABLE IV.—OUTPUT IN AMPERE-HOURS. (For Cell No. 3.)

Time in hours.	Current in amperes.	P.D. in volts.
0	1·1	1·173
·16	1·1	1·171
·33	1·1	1·169
·50	1·1	1·168
3·00	1·1	1·152
7·5	1·1	1·145
12	1·1	1·124
31·1	1·1	1·115
55	1·1	1·102
78·75	1·1	1·085
112	1·1	1 079
184	1·1	1·059
188·5	1·1	1·029
226·5	1·1	1·015



RESULTS AS PLOTTED FROM TABLE IV. (For Cell No. 3.)

The gain in the voltameter plate was 292 628 grammes, which gives an output of 250 ampere-hours.

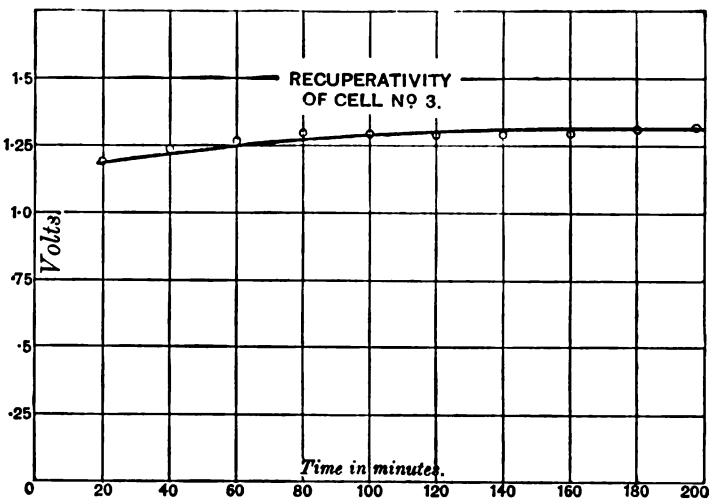
Weight of zinc used	·69lb.
Theoretical weight of zinc required for the above output was only	·671b.

This gives the very high efficiency of 97 per cent. This result is better than that of any primary cell I have yet tested.

RECUPERATIVITY.

TEST III. TABLE V. (For Cell No. 3.)

Time in minutes.	E.M F. in volts.	Time in minutes.	E.M F. in volts.
20	1 191	120	1 285
40	1 236	140	1·289
60	1·260	160	1·293
80	1·281	180	1·318
100	1 283	200	1·328



RESULTS AS PLOTTED FROM TABLE V.

TEST IV.—INTERNAL RESISTANCE.

The potential difference at the end of each period of five minutes was deducted from the total E.M.F. at the end of each period. This gave the fall of voltage or pressure inside the cell. Then this internal voltage or fall of potential inside the cell, divided by the current at the time, gave the apparent internal resistance of the cell.

$$\text{By Ohm's law, } C = \frac{E}{R} \quad \therefore \quad r = \frac{E - (P.D.)}{C},$$

where r represents the internal resistance of the cell (see curves). From this formula (as calculated from Tables II. and III.) the mean internal resistance of the two battery cells were 0·112 and 0·161 ohm respectively.

TEST V.

Having also received from you a specimen of your combined three-cell oval type, with a request to test the same, I have much pleasure in stating that in all respects it has proved as satisfactory as the previous ones. This battery consists of a combination of three cells, joined in parallel. Each cell, however, is similar in internal construction to those already described, but the carbon of each cell is surrounded by a thin perforated metal cylinder instead of the earthenware containing vessel, while another oval perforated vessel of the same material surrounds the three cells. This greatly reduces the weight for a given output. The total length, including the insulated handles, is 21in. by 5½in. broad and 11in. high, the weight being approximately 30lb. Each set of three cells is intended to give a current of six amperes at about one volt potential difference.

TABLE VI.—TOTAL OUTPUT. (For the Three-Cell.)

Time in hours.	Current in amperes.	P.D. in volts.
0	6·1	1·145
1	6·1	1·140
18	6·0	1·134
19	6·0	1·134
22	6·0	1·134
24	6·0	1·130
42	6·0	1·122
44	6·0	1·122
48	6 0	1·110
72	6·0	1·090
76	6·0	1 072
77	6·0	1·042
95	6·0	1 022
97	6·0	1·022
102	6·0	1 020
104	6·0	1·020
125	6·0	1·010
128	6·0	1·000

My first test gave an output of 324 ampere-hours with a very small diminution of voltage, but after this output the cell was allowed to run down by mistake, between a Friday night and Monday morning, and thus the exact total output could not be ascertained. The same cell was, however, then cleaned out and freshly charged with your caustic solution, whilst the zincs were carefully re-amalgamated. A copper voltameter was placed in circuit, and the cell again started. A Weston standard voltmeter and a milliampere-meter were placed in circuit, and readings of

Digitized by Google

the current and potential difference were simultaneously noted throughout the trial.* The results were as shown in Table VI., which shows that the cell kept a remarkably constant current with a slight fall in voltage. I have therefore much pleasure in affirming that your non-polarising cell is the best of its kind that I have ever tested. I believe that it will prove very serviceable for driving electric motors, for electric lighting, and for the electro-deposition of metals, where engines and dynamos are not available. Finally, I have pleasure in thanking my assistant, Mr. David A. Ramsay, and two of my students, Messrs. Stephen Hutchison and Alexander Nisbet, for their kind assistance and perseverance in arranging and taking the many readings, which these long continuous tests involved.

PHYSICAL SOCIETY.

An extra meeting of this society was held on November 11, 1894, in the physical laboratories of University College (by invitation of Prof. Carey Foster), Prof. Rücker, president, occupying the chair.

Prof. Ramsay read a paper, by himself and **Miss Dorothy Marshall**, on "**The Measurement of Latent Heats of Vaporisation of Various Organic Liquids.**" The liquid to be examined is placed in a small flask with a narrow neck, and within this is a platinum wire, which has its two ends fixed through the bottom so as to be capable of conveying an electric current and thus giving heat to the liquid. The flask is completely enclosed in a jacket, which is filled with the vapour of liquid of the same kind kept briskly boiling in a somewhat larger flask. Before the current is turned on the vapour jacket is kept going for some time, so that the liquid in the flask is raised just to its boiling point, but no appreciable evaporation takes place. As soon as the current is turned on boiling commences, and as the temperature of the liquid cannot be further raised all the heat developed in the wire is expended in producing evaporation. By weighing the flask before and after, the mass of liquid vaporised is determined. So far the authors have only used the method for comparative determinations. Two arrangements of the kind described are placed side by side, and the same current is sent through their two wires, which are joined in series, and have approximately equal resistances. The actual values of the resistances are found while the current is flowing, and allowance is made for their inequality. The ratio of amounts of heat expended on the two liquids, divided by the ratio of the masses vaporised, is equal to the ratio of their latent heats. As a standard liquid of known latent heat, the authors prefer alcohol to water, as it vaporises more easily and with less bumping. The determinations made by this method agree well with those of other observers, but the authors' object is to obtain values correct within about ½ per cent. for a large number of liquids rather than a highly accurate value for any one substance. In reply to **Mr. Griffiths**, the authors stated that the platinum wire was found to rise about 20deg. above the temperature of the liquid, and Mr. Griffiths said that his experience had been similar. He did not see why a very high degree of accuracy should not be obtainable by the method. **Prof. Rucker** expressed his admiration for the work, and thought it justified by the fact that the results accorded more nearly with theory than those of other observers.

Mr. Rumorfopoulos read a paper on "**The Determination of Thermal Conductivity and Emissivity.**" In the first series of experiments described, two bars of the same material and polish, and each of uniform circular section, are heated, each at one end, until the distribution of temperature has become steady. By means of two thermo-joints (one on each rod) a series of isothermal points are then found. According to the ordinary theory, if the two bars agree in temperature at a given pair of points, they will also agree in temperature at distances x_1 and x_2, measured respectively from these points, where x_1 and x_2 are connected by the relation $x_1/x_2 = \sqrt{(r_1/r_2)}$, r_1 and r_2 being the radii of the rods. This relation was not found to hold good for the rods examined, some being of brass, others of copper and of German silver. In all cases x_1/x_2 was further removed from unity than the ordinary theory would require. One conclusion was that the formula usually adopted in such cases could not be used for the comparison of conductivities unless the radii of the rods compared are equal, and their surfaces in the same condition, for it seemed unlikely that the thermal conductivity of the smaller of each pair of rods was less than that of the thicker one. To settle the question, three brass rods were chosen, and their absolute conductivities compared by Angström's method, one end of the rod being alternately heated and cooled, and the alternations of temperature observed at two points along the rod as soon as they had assumed a periodic character. At each point of the bar the excess of temperature over surroundings may be analysed into a Fourier's series, consisting of a constant term and series of sines and cosines. Hence both emissivity and conductivity were calculated. The emissivity was found to vary considerably with the radius, being greater the thinner the rod; moreover, the value of the emissivity deduced from the first sine term of the Fourier's series was in each case found to be about 1·2 times as great as that deduced from the constant term.

Mr. G. U. Yule then gave a brief outline of his paper "**On the Passage of an Oscillator Wave-Train Through a Plate of Conducting Dielectric.**" By a conducting dielectric the author means a substance whose conductivity and dielectric capacity are both of importance in the case under discussion, and the paper is mainly an investigation of the following problem: a train of plane electromagnetic waves falls at normal incidence on an infinite parallel-sided plate of conducting dielectric, whose thickness is finite, and at the first face of the plate the amplitude of the vibration-vector in the incident train is zero up to a certain instant, and then becomes equal to an harmonic function of the time, multiplied by an exponential function with negative index. To find what proportion of the energy of the whole incident train is reflected back, what proportion is transmitted through the plate, and what proportion absorbed at successive incidences of reflected and re-reflected wave-trains upon the two bounding faces of the plate, the amplitudes and phase-changes of reflected and transmitted portions have to be taken into account, and the resulting infinite series of terms have to be summed. The analysis is very long, but the results obtained are exact. Curves are given, showing (for special numerical values of the constants of the problem) the quasi-periodic variation of the amounts of energy transmitted and reflected, as the thickness of the plate is increased from zero up to a high value. Other curves are given showing the effect of varying the dielectric constant and the conductivity of the plate, and the difference between a "damped" and an "undamped" wave-train in regard to intensity of reflected and transmitted portions. The author compares his calculated results with measurements obtained in the case of oscillator waves travelling along a double-wire circuit about 100 metres in length, the wires at the middle of the circuit being run through a jar containing distilled water, alcohol, or a very dilute electrolyte. The necessary corrections, however, are difficult and uncertain, and the author has not found it possible to deal with them in a satisfactory way.

A letter from **Dr. E. H. Barton** was read, emphasising the necessity for taking into account the damping in the oscillator train, and at the same time pointing out why, in his opinion, the corrections applied by Mr. Yule were inadequate and failed to yield intelligible results.

Prof. Rucker congratulated Mr. Yule on his work and on the importance of the results he had obtained. In returning the thanks of the society to Prof. Carey Foster for the invitation to meet in University College, he expressed the pleasure he had felt in observing the extent and completeness of the laboratories. Hitherto London had been behind the provinces in this matter, and it was gratifying to find that students in London had now such opportunities for practical instruction in physics. The papers which had been read at that meeting were a proof that good use was being made of the laboratories for the purposes of research. The educational experiments they had seen in the laboratories were excellently devised, and he hoped that many of them would become a part of the regular course of instruction in the country.

Prof. Foster briefly replied.

SPECIAL REPORT OF THE BOARD OF TRADE UNDER SECTION I. OF THE ELECTRIC LIGHTING ACT, 1888.

The following report, dated May, 28, 1894, has been issued from the Board of Trade by Mr. Francis J. S. Hopwood, assistant secretary:

The Holloway Electricity Supply Company, Limited, applied for a provisional order in respect of the borough of Guildford. The Corporation, who are the local authority under the Electric Lighting Acts, consented to the application on condition that the order should contain a provision authorising them to purchase the undertaking within six months from the expiration of 10 years from the grant of the order, or within six months from the expiration of any subsequent period of five years on the terms specified in Section 2 of the Electric Lighting Act, 1888. The order, when deposited, did not contain a provision to this effect, and the Corporation objected to it, and stated that they were considering whether they should not adopt measures for supplying electrical energy themselves.

The promoters contended that the conditions asked for by the Corporation were unreasonable, and would prevent them from raising the necessary capital for the undertaking, and asked the Board of Trade to dispense with any further consent of the Corporation, and to grant the order in the usual form, or with such modifications of the statutory conditions of purchase as the promoters could agree to. Before deciding whether the application should be proceeded with, the Board of Trade invited the representatives of the Corporation and the promoters to attend at this office to discuss the matter. A meeting was held on March 31, at which the Mayor of Guildford and the town clerk, who attended on behalf of the Corporation, stated that the Corporation desired to retain in their own hands the right to supply electrical energy to the town, but that they had several public works on hand, and were not prepared to apply for a provisional order at present or to place any limit on the time within which they would apply. They stated that the Corporation would, however, consent to the grant of the order on the conditions originally agreed to by them.

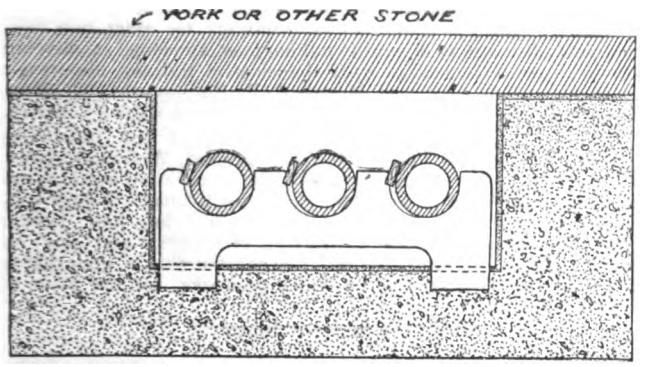
The representatives of the Corporation were informed that as the Corporation were not prepared to give any undertaking as to

* The Weston meters had been most been most carefully compared with Lord Kelvin's latest standard balances and found to be correct.

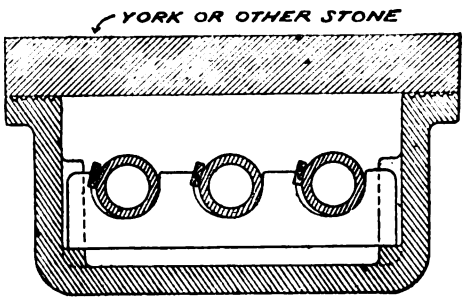
Digitized by Google

the period within which they would apply for an order, the Board of Trade would not be justified in refusing to proceed with the promoters' application. The Board were unable, however, to impose on the promoters the condition as to purchase asked for by the Corporation, which appeared to them to be an unreasonable modification of the terms established by Parliament, but they intimated their readiness to consider any further proposals the Corporation might submit. Subsequently, the Corporation suggested that the period at which the option of purchase on the terms of Section 2 of the Electric Lighting Act, 1888, should arise should not exceed 30 years.

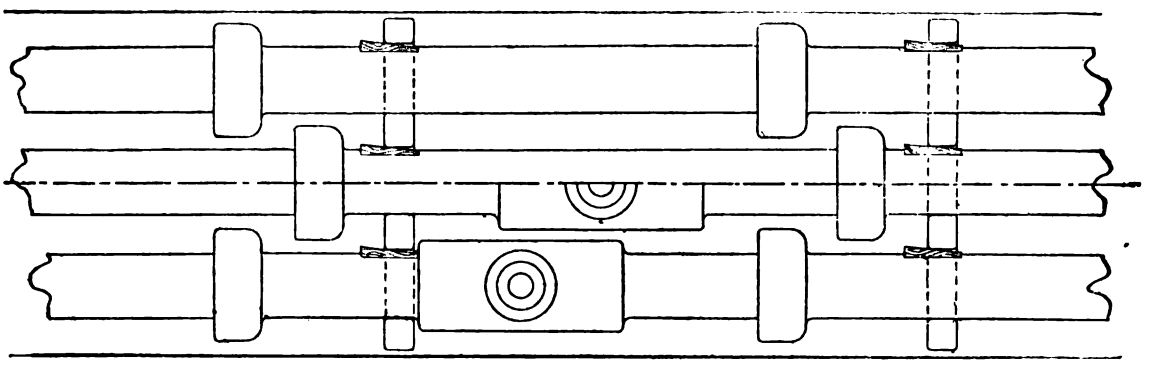
The promoters were unable to accept this proposal, and urged that a reduction of the statutory term was not reasonable without some corresponding concession on the part of the purchasing authority. On the suggestion of the Board of Trade, however, they agreed to accept a provision that the period of 42 years fixed by the Electric Lighting Act, 1888, should be reduced to 35 years, and the Board of Trade decided to grant the order on these terms. This decision was communicated to the Corporation, with an intimation that the Board of Trade would be glad to hear that they were prepared to give their consent. The Corporation, however, replied that they were not prepared to consent to the grant of the order in the form proposed.



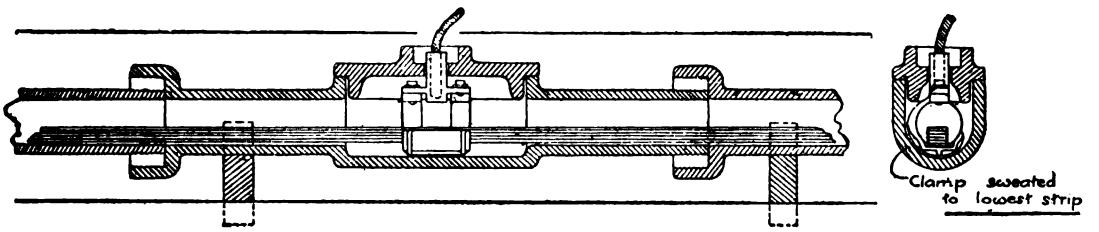
The Spence-Doulton System in Concrete Culvert.



The Spence-Doulton System in Earthenware Culvert



Plan of Culvert.



Sections of Junction-box, showing Method of Making Branch Connections.

THE SPENCE-DOULTON CONDUIT.

In the accompanying illustrations is shown a new type of conduit designed for the reception of bare copper mains. It will be noticed that the principal object in view has been to combine the advantages of the drawing-in system with those accruing through the use of copper strip laid in culverts. The conduit, as will be seen from the cross-sections, is composed of vitrified stoneware tubes, carried on insulating bridges of the same material, and laid in a culvert or trough. A special type of joint which does not necessitate the use of cement is used, this being to all intents and purposes an artificial "bored and turned joint." This joint is watertight, and surface leakage is thereby prevented. A plan of the conduit showing straight pipes and junction-boxes, and sections of the junction-box representing the method of making branch connections, are annexed. This method of underground conduits has been introduced by Messrs. Doulton and Co., of Lambeth, S.E., who state that, in addition to the insulation afforded by the tubes, the bridges form a further safeguard, thus ensuring a high insulation resistance. The company claim that this system allows additional copper strips being laid down with greater facility than that of drawing insulated cables into cast-iron pipes; that existing conductors do not need to be hauled out before new ones can be drawn in; and that as there is no insulation coating to be abraded, or to weight the strip, the surface boxes may be arranged further apart than is the case where insulated cables are employed. As regards service connections, the junction-boxes, as shown, are simple, and they can be placed at small cost opposite every alternate party wall. If, however, a connection is required where no provision has been made, it is only necessary to remove a short length of the pipe and replace it with a modified one. The company supply earthenware troughs for the accommodation of the conduit. These troughs, which can be more rapidly constructed than those of concrete, are fitted with socket joints for Portland cement, and are provided with lugs for keeping the bridge insulators in position.

ELECTRIC LIGHTING IN THE CITY OF LONDON.

The directors of the City of London Electric Lighting Company, Limited, have decided to allow discounts to customers in accordance with the following scale:

5	per cent. off an account amounting to.....			£100
7½	,,	,,	,, ...	200
10	,,	,,	,, ...	400
12½	,,	,,	,, ...	550
15	,,	,,	,, ...	700
17½	,,	,,	,, ...	850
20	,,	,,	,, ...	1,000

The accounts will be issued, as hitherto, at 8d. per Board of Trade unit, and the discount under the above scale will be allowed in those rendered for the last quarter of the year, provided the account for each quarter is paid within one calendar month from the last day of such quarter, and no consumer will be entitled to any discount until he has been supplied for a complete year from January 31 to December 31. A consumer connected to

Digitized by Google

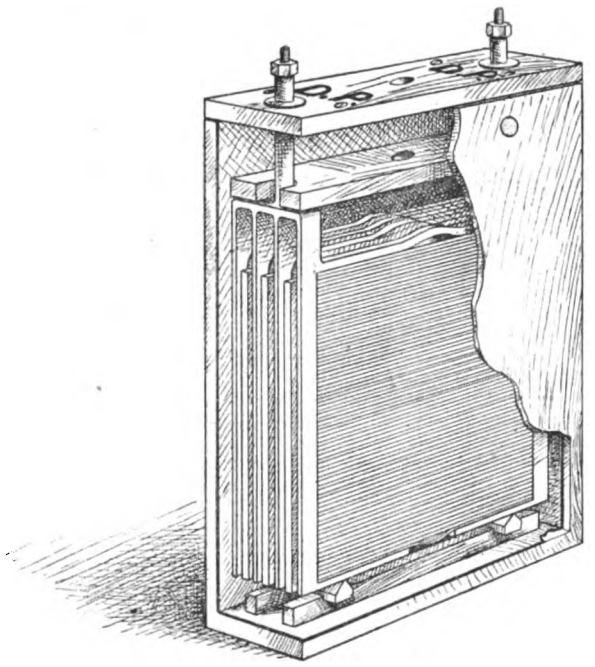
the Company's mains at any date between January and December will not be allowed discount until after the expiry of 12 months, dating from the following December 31 after his connection. He will then receive discount, based upon his annual consumption, for the whole time he has been connected. A customer taking current for less than 12 months will not be entitled to any discount. Each tenancy in a building is to be treated as a separate consumer.

The rate for current for lighting at night (between the hours of 10 p.m. and 6 a.m.) and for motive power, heating, and cooking purposes will remain for the present 4d. per Board of Trade unit, and will not be subject to the above scale of discounts. The Board have also authorised the following reduction in the quarterly rental of meters: up to 50 lamps of 8 c.p., from 5s. to 2s. 6d.; above 50 lamps, for every additional 50 lamps or part of 50 of 8 c.p., 2s. 6d.

The above alterations take effect as from 1st inst.

TRAIN-LIGHTING BY STORAGE BATTERIES.

The lighting of railway trains by means of storage batteries has been more generally introduced on the Continent than in this country, and we are now glad to learn that Messrs. Johnson and Phillips are moving in this direction. The firm, who have been encouraged by the great success of the "D. P." battery during the last five years, are now bringing out an adaptation of it for train-lighting. The new cell is shown in the illustration, and its features, compared with other well-known types, are smallness of space occupied, reduced weight, large space between the plates (preventing short-circuiting and collapse of cells), and great mechanical strength and high efficiency.



These qualities, combined with the well-known advantages of the battery in point of durability, render it specially suited for train-lighting work. The particular cell represented in the illustration is the "B" size; 220 ampere-hours capacity, the outside dimensions being 6½in. by 10¾in. by 17¾in. high, and the weight 92lb. These cells are produced by a special electrolytic process, which is entirely free from any patents held by other makers.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Saint-Dié (Vosges, France).—The Municipality invite tenders by February 1 for the concession for a central electric light station for the town.

Louvain (Belgium).—Tenders are invited by February 1 by the local authorities at the Hotel de Ville for a concession for an electric tramway from the railway station to the Grand Place, Louvain.

Bristol.—Tenders are invited for the installation of the electric light at the Guildhall and a portion of the Council House, for the Corporation. We have already given particulars. Tenders must be sent in by to-day.

Nelson.—Tenders are invited for lighting Stanley-street Chapel, Nelson, by electricity. Particulars are obtainable from Mr. James Bateson, 10, Primrose-street, Nelson, to whom tenders are to be sent by to day.

Lisbon.—Tenders are invited by 31st inst for telegraphic apparatus and porous jars by the Royal Portuguese Railway Company, of Lisbon. Particulars are obtainable from the bureau of the Compagnie Royale des Chemins de Fer Portugais, 28, Rue de Châteaudun, Paris.

London.—The Metropolitan Asylums Board invite tenders for the supply and running of mains, and the wiring of the buildings and grounds of the North-Western Fever Hospital, Haverstock-hill. We have already given particulars. Tenders are to be delivered not later than Thursday, the 24th inst.

RESULTS OF TENDERS.

Coventry.—The City Council have accepted the tender of Messrs. Chamberlain and Hookham, Birmingham, for the supply of meters.

Hampstead.—The Vestry have accepted the tender of Mr. Frederick H. Taylor, at £68, for fitting up buildings in the stone-yard for the electric light.

Broadhembury.—The tender of Messrs. Hearden and Son, of Plymouth, has been accepted for fixing a lightning conductor to Broadhembury Church, near Honiton.

Aberdeen.—The tender of Messrs. New and Mayne for wiring, for electric lighting, the Municipal Buildings, for £200, has been accepted. For supply of additional engines, dynamos, steam and exhaust pipes in connection with the electric lighting station in Cotton-street, the tender of Messrs. J. H. Holmes and Co., Newcastle-on-Tyne, at £3,270, has been accepted by the Town Council.

Walsall.—The Town Council have accepted the following tenders—viz., one by Thomas Parker, Limited, Wolverhampton, for supplying plant (except mains) for the generating station, for the sum of £5,061; one by the Callender Bitumen, Telegraph, and Waterproof Company, London, for supplying and laying down the electric mains, for the sum of £3,998; and one by Mr. H. Gough, Wolverhampton, for constructing a generating station at the Wolverhampton-street gasworks, for the sum of £1,750.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,924.

The Electrophone, Limited.—Letters of allotment and regret have been posted by the Electrophone, Limited.

Lancaster.—The committee of the Central Conservative Club, Church-street, have lighted the club premises by electricity.

Bury.—The Town Council will apply to the Local Government Board for powers to borrow £30,000 for a central electric station.

Lambeth.—The Vestry have decided to thoroughly go into the question of electric lighting, in order to see how the matter stands in the parish.

Worcester.—Mr. Ruthven Murray, of the Aberdeen municipal electric light station, has been chosen as electrical engineer to the Worcester Corporation.

Bristol.—The Electrical Committee have held a meeting, at which Mr. Hill was appointed third assistant engineer, in the place of Mr. Bell, resigned.

Waterloo and City Railway.—The second half-yearly general meeting of this Company will be held at Waterloo Station on Thursday, February 7, at 2.30 p.m.

Direct United States Cable Company.—Payment is announced on the 26th inst. of a quarterly interim dividend of 2s. per share, £3,000 being placed to reserve and £1,807 carried over.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 13th inst. amounted to £866, as compared with £665 in the corresponding week of last year.

Ferranti Alternator.—A 1,000-unit alternator, to give 100 amperes at 10 000 volts, has just been ordered of Messrs. S. Z. de Ferranti, Limited, by the London Electric Supply Corporation.

The City.—The accounts of the City Commissioners of Sewers show that in the year ended September 29 £13,052. 12s. 11d. was paid to the City of London Electric Lighting Company for public lighting.

Brighton.—The question of lighting the Marine-parade by electricity came up again on Thursday (yesterday) upon a letter from Councillor Blaker requesting the committee to reconsider the matter.

Protoria.—For attending to the arc lamps in the public thoroughfares, three of Heathman's patent Brighton pattern wheeled extension ladders have just been ordered to be shipped to South Africa.

Blackrock (Ireland).—A communication has been received by the Blackrock Commissioners from the electric tramways company stating that they would commence the laying of their new line on February 1.

Queenstown.—A proposal is on foot that an electrical engineer should be engaged to report on the practicability of using the present pumping-engine machinery in connection with a scheme for lighting the town electrically.

Bangor (Wales).—In reference to the Electric Lighting Acts, the clerk to the Town Council, as requested by the committee, has prepared a report, which has been ordered to be printed, and copies are to be supplied to the members.

Huddersfield.—In moving the minutes of the Electric Lighting Committee at a meeting of the Town Council on Wednesday, Mr. Calvert stated that the number of consumers had increased from 89 in January, 1894, to 214 in January, 1895.

Digitized by Google

Fareham.—The late Local Board applied to the Local Government Board to borrow £7,000 for buying the works of the local electric light company. Their successors—the District Council—however, are moving in an opposite direction.

Babcock and Wilcox, Limited.—The Board have declared interim dividends at the rate of 6 per cent. per annum on the preference shares and at the rate of 10 per cent. per annum on the ordinary shares for the six months ended December 31.

Portsmouth.—The Electric Light Committee of the Town Council have ordered a hundred electricity meters, and mains will be extended to Arundel-street, Marmion-road, Castle-road, Lake-road, St. Mary's-road, and the infectious diseases hospital.

Bootle.—The Town Council have decided that the sum of £4,300, sanctioned by the Local Government Board for alterations to the Town Hall and other municipal buildings, and for lighting the same by electricity, be borrowed from the Yorkshire Penny Bank, of Leeds.

Consolidated Telephone Company.—The Consolidated Telephone Construction and Maintenance Company, Limited, state that it has been arranged to cancel the heads of agreement between that Company and the Pneumatic Typewriter Company respecting the manufacture of typewriters.

Frizington.—A meeting has been held of the Arlecdon and Frizington Urban District Council at which Mr. Richards gave notice of motion to consider the question of lighting the district with electricity. He asked the clerk to prepare for next meeting an estimate of what their present light had cost them for the last three years.

Llanelly.—The construction of large municipal buildings has induced the local authority to consider the question of lighting the new Town Hall, the Athenæum buildings, the new Market Hall, the market premises, and the chief streets of the town by means of electricity, and the borough surveyor has been instructed to report to the Board.

Carbon Rods and Battery Plates.—Messrs. Krupka and Jacoby inform us that they have transferred their business to 15, Queen-street, Cheapside, E.C., where they keep in stock carbon rods, battery plates, agglomerate blocks, and dry batteries, manufactured by Dr. Alb. Lessing, of Nürnberg, contractor to the German Imperial Government.

Kendal.—The Town Council have taken into consideration a minute of the Electric Lighting Committee, recommending the Corporation to give notice of objection to the granting of a provisional order to the Windermere and District Electricity Supply Company. Councillor Jefferys moved the adoption of the recommendation of the committee, and this was agreed to.

Ottoman Railways and Public Works Corporation, Limited.—This Company has been registered with a capital of £550,000 to acquire conventions, firmans, concessions, rights, or privileges for the construction of railways, tramways, or other public works, granted, or to be granted, by the Sultan of Turkey, or the Sublime Porte, or any other sovereign State, Government, or any other authority.

Appointment Vacant.—The Southampton Electric Light and Power Company require a man accustomed to bare copper mains and low-pressure three-wire system to act as outside foreman on mains, house services, etc. The wages are 30s, and uniform. Applications, giving testimonials and stating past experience and age, are to be sent to the engineer, Back of the Walls, Southampton.

Sheffield.—A local paper states that on Wednesday evening the users of the electric supply from the works of the electric light and power company experienced the annoyance of the stoppage of the supply. The explanation of the company is practically that the mishap is due to their desire to supply the full demands of their customers, and that in the attempt the old machinery has been overtaxed. They ask for the forbearance of the public until the new plant is ready.

Oswestry.—Complaints are being made in the Council with respect to the quality and price of the gas. Councillor Williams said that he would suggest that the Council communicate with the Oswestry Electric Lighting Company with a view, if it were thought advisable, of taking over their concern. Councillor W. T. Jones said that he understood the company was practically dead. Councillor Ellis remarked that it had never lived, and consequently could not be dead.

Dover.—It has been stated at a meeting of the Town Council that the bill for the work carried out by the Council in connection with the laying of the electric mains amounted to £138. 1s. for December. £1,322. 13s. 9d. has been so far spent on labour and materials in the portion of the work done by the Council's men, for which the Corporation will be repaid. The use of the steam-roller was granted to Mr. H. Stiff on the usual terms to make a roadway round the electric light works.

Bath.—Mr. Gatehouse, the electric light inspector to the Town Council, reported to the latter last week that there had been 34 failures during the fortnight. He stated that nearly the whole of the 34 lamps were extinguished on account of the bad quality of the carbons. These contained siliceous matter which during combustion fused into a species of glass, thereby stopping the working. It was agreed that a representation be made to the electric lighting company.

Battersea.—In view of the applications which are being made by private companies for permission to lay down mains in the district for supplying the electric light, the Battersea Vestry have resolved to enter formal notice of opposition, and have also appointed a special committee to consider and report as to the advisability of the local authorities undertaking the supply on their own account. The committee which was appointed at the last meeting of the Vestry consists of 13 Progressives and seven Moderates.

Grasmere.—Correspondence has been read at a meeting of the Urban District Council from the electric light company and Mr. Gatey, and some discussion arose as to opposing their application to the Board of Trade for a provisional order. Mr. Armstrong said the proper course to take was to suggest a joint committee to act with the neighbouring Boards. The question would then be thrashed out, and time would be saved. It was agreed that the chairman and vice-chairman be appointed to meet members of the other Boards and consult on the question.

City and South London Railway.—The receipts of the Company for the week ended January 13 were £1,001, against £951 for the corresponding week of 1894, or an increase of £50. The total receipts for the current period of the present half-year are £2,005, against £1,941 in the corresponding period of 1894, an increase of £64. For the half-year just ended the Board announces a dividend on the ordinary stock at the rate of 1¼ per cent. per annum, £950 being carried over. The dividend for the corresponding period was at the rate of ¾ per cent. per annum, when £1,063 was carried over.

Crompton and Co., Limited.—This Company have this week invited subscriptions for £100,000 5 per cent. first mortgage debentures at par. The business has been carried on as manufacturers of electrical plant by a limited company since 1888, and the average net profits for the past six years, it is stated, have been £10,320 per annum. The debentures will be repayable at par on January 1, 1920, but the Company reserves the option of repaying any portion of the bonds by April, 1900, at 5 per cent. premium, or earlier by purchase in the market, or at six months' notice at the price of £110 per cent.

Chard.—Councillor E. Gawler suggested at a recent meeting of the Town Council the desirability of the Council acquiring the Chard reservoir—a sheet of water about 70 acres, formerly used for supplying the canal between Chard or Bridgwater—as a recreation place for the town. He thought the reservoir and the surrounding land might be made a favourite pleasure resort, and the water might be utilised as power for lighting the town with electric light. The idea was favourably entertained, but was deemed impracticable at the present time in view of the many other matters pressing for the attention of the Council.

St. Helens.—A monthly meeting of the St. Helens Corporation Water Committee has been held, when the Baths Sub-Committee recommended certain repairs to the baths in Warrington Old-road. Alderman J. C. Gamble remarked that several members of the Gas and Lighting Committee had inspected the baths, and they thought that the building would be very suitable for the generation of electric light when the Corporation completed their arrangements for its supply within the borough. It was decided that the Baths Sub-Committee and the Gas Sub-Committee should jointly consider the matter and present a report at a future meeting.

Ealing.—A letter has been read at a meeting of the Urban District Council from a Mr. Baker making a claim upon the Council in respect of an alleged infringement of a patent held by him of an apparatus used in connection with the machinery laid down for the electric light. The surveyor advised that the claim could not be sustained, and the Council resolved that they could not entertain it, though they formally referred the letter to Messrs. Bramwell and Harris, the consulting engineers employed under the electric lighting scheme. The new Electric Lighting Committee consists of the following members: Messrs. Box, Hedges, Baker, Hays, Kasner, and Thayers.

Ventilation of Manholes.—Messrs. Peirson and Co., of 124, Fenchurch-street, E.C., have drawn our attention to their "Simplex" ventilating system for electric light manholes, sewers, coal and other cellars, and all underground work where it is connected with roads. The system consists in the use of tubes, the position in which the ventilating tubes are fixed relatively to the cableways, gas or sewer pipes, etc., bringing about, it is claimed, a complete circulation of air in the manhole, and consequently preventing the dangerous accumulation of gas therein. The ventilator pipes are strongly made in cast iron, and with the readiest means of cleansing and repairs.

Folkestone.—The Town Council have held a meeting at which a letter was read from Mr. W. G. F. Webster offering to enter into an engagement to light the Leas with electric light for a term of years, at the end of which time the Corporation would be able to purchase the plant, etc., if they thought fit. He said his present plant was ample for the purpose, and he referred the Corporation to the installations he had already put in. The Corporation could, if they pleased, have their own cables and wires. The letter was referred to the Lighting Committee to consider. The names of Councillors James and Peden have been added to the last appointed Electric Light Committee.

Telephony at Leeds.—The National Telephone Company asked leave some months ago from the Leeds Highways Committee to lay a number of wires under the pavements of the city instead of overhead. The committee decided to comply with the request if the company would undertake to pay an "acknowledgment" of 5s. in respect of every subscriber who might use the wires. The company, however, protested against this impost, and pleaded that the postal authorities paid nothing, or only a nominal sum for the right to lay telegraph wires underground. The committee, however, declined to give way, and there the negotiations seem to have ended, for all additional wires are being erected in the air.

Digitized by Google

Industrial Inventions Development Company, Limited.—This Company has been registered, with a capital of £50,000 in £1 shares, to enter into and carry into effect an agreement, which has already been prepared, and is expressed to be made between this Company and F. L. Lawson for the purchase of an interest in certain inventions therein mentioned; to apply for, purchase, or otherwise acquire, use, exercise, develop, grant licenses in respect of, or otherwise turn to account any patents, *brevets d'invention*, licenses, etc., and to carry on business as bankers, capitalists, financiers, concessionaires, merchants, etc.

Richmond.—The Finance Committee of the Town Council have reported that the electric lighting company have now deposited £50 in accordance with the resolution of the Council, and that there was also £67 still remaining deposited in accordance with the contract. The clerk to the Richmond Main Sewerage Board has read a letter from the Board's contractors for the electric light installation, Messrs. Drake and Gorham, suggesting a periodical inspection of the Board's electric lighting installation. The cost would be £3. 3s. a year and travelling expenses. The Engineer, in reply to a question, said that if the Board tested the installation themselves the first cost of the apparatus would be very heavy. It was resolved to accept the offer if the contractors would accept £4. 4s. a year inclusive.

Anglo-American Telegraph Company, Limited.—At a meeting of the board of directors, held on Friday last, it was resolved, after placing the sum of £12,000 to the credit of the renewal fund, to recommend to the proprietors the declaration of the following dividends: (1) a balance dividend of 14s. per cent. upon the ordinary consolidated stock; (2) a balance dividend of £1. 8s. per cent. upon the preferred stock, both payable on January 26 next, less income tax. After paying the dividends, there will be a balance of about £485 to be carried forward to the next account. The dividends, together with those already paid, will amount to £2. 2s. per cent. on the ordinary consolidated stock and £4. 4s. per cent. on the preferred stock for the year 1894. The register of transfers will be closed till January 25.

Walsall.—In connection with the tenders sent in for the central electric light station, to which reference is made in another column under "Results of Tenders," the town clerk has read correspondence which had passed between the Electric Construction Company and himself upon a complaint by the former that they had been unfairly passed over, and had not had an opportunity of sending in an amended tender. Since the Council assembled, a communication had been received from the chairman of the Electric Construction Company, addressed to the Mayor, stating that the company were largely influenced in the negotiations for the restarting of the electric trams by the understanding that the Corporation were favourably considering the company's tender for the electric works. The Town Clerk and the Mayor denied that there was any such understanding.

Newington, S.E.—The Clerk to the Vestry stated that he had received notice from the County of London and Brush Provincial Electric Lighting Company, Limited, of their intention to apply to the Board of Trade for a provisional order to authorise and empower the company to produce and supply electricity within the area of the parish. He asked for instructions, having regard to the resolution adopted by the Vestry on November 16, 1892, opposing the granting of the order to the company. Mr. Smithers said none of them would care to see a company come to Newington and obtain the provisional order, and the Vestry would do well to prevent another monopolist arising in their midst. He thought they ought soon to have their parish better lighted—it would mean a lower police rate. He moved that the company's application be opposed by the Vestry. Mr. Hammond seconded, and the motion was carried.

Taunton.—The Town Council have adopted the following report, which was submitted by the Electric Lighting Committee: "Your committee report that the Local Government Board has sanctioned the borrowing of £5,000 for purposes of electric lighting, to be repaid in 25 years from the date of borrowing—the works in connection with the No. 2 sub-station will be proceeded with at once. Your committee report that the arrangement with Mr. Newton as to the testing and subsequent purchase of his transformers has fallen through, and they ask the Council to authorise them to obtain the transformers required for the No. 2 sub-station elsewhere. Your committee recommend that the collector collect the accounts connected with the electric lighting undertaking at a fixed sum of £15 a year, and that the borough accountant keep the accounts in connection therewith at an extra salary of £15 a year."

Chelsea.—The Chelsea Electricity Supply Company have submitted a tender to the Chelsea Vestry for lighting some of the streets of the parish with electricity. The cost to the Vestry of the lamps to be lighted during ordinary lighting hours would be £28 per lamp per annum, with a minimum of 50 lamps, the contract for lighting to be not less than seven years in duration. The lamps and lamp-posts cost from £25 to £30 each, and will be provided by the Vestry, the cost of the mains and cables necessary for conveying the supply of electricity to the lamps being borne by the company. The price of £28 will include the maintenance of the lamps in working order. The painting and glazing of the lamp-post and lantern will be done by the Vestry. The cost of gas over the area proposed to be treated is £574, while the cost of electricity on these conditions will be £1,400. The matter will be considered at the next meeting.

Dublin.—Dealing with matters municipal at a meeting of the Dublin Corporation, at which Alderman Dillon was re-elected Lord Mayor for 1895, the Mayor stated that in their paving work they had carried out the usual amount of work. In this connection they would have before them an application from the tramway company of a most interesting character. They were seeking powers to run the tramcars over the streets by means of electricity, and he trusted the Council would view this matter with favour so that such an improved means of locomotion would be secured for the city. Another important question was that of the lighting of the city. The electric lighting had proved eminently successful during the year. Last year they had 140 customers; now they had 196. They now had 16,600 lamps. Consumers had ordered many more, and their plant was now almost completed, so that they would be able to meet the demand.

Windermere.—The chairman of the District Council, on behalf of the committee appointed to consider the draft electric lighting order, reported that the committee had discussed the matter in conjunction with committees from Ambleside and Bowness. A document named "the Ulverston agreement" was placed before them, with which they did not thoroughly agree. In the end it was unanimously resolved, so far as Bowness and Windermere were concerned, to agree to the provisional order, as they considered that in it the interests of the public were sufficiently safe guarded. Mr. Fell said he had seen the engineer of the scheme that day, who had told him that whatever arrangement was the best arrangement with any of the different authorities would also apply to the whole of them; so that if any portion of the district was able to get any better terms, those terms would apply to Windemere. The report of the committee was adopted.

Dundee.—A report by Mr. George Baxter, the water engineer, was submitted on Tuesday to the Water Committee of the Town Council upon the available supply of water from the gathering grounds, the present capacity of the works, and other matters bearing on the question of increased consumption of water for trade and other purposes. With regard to the utilisation of surplus water, Mr. Baxter says: "The power required at the electric lighting station is fully 700 h.p., and the power that might be obtained by the fall of our water into Stobsmuir would not exceed 9 h.p. I may point out that the question of water power for the electric lighting of the city was fully considered by the previous convener when the scheme was in hand, and so far as the public water supply was concerned, it did not require very serious consideration to arrive at the opinion that no help could be derived from it."

Bowness.—A meeting of the Urban Council has been held, at which the Chairman said the Lighting Committee had met the solicitor of the electric lighting company at Rigg's Hotel, and after examining the agreement which the company had made with the Ulverston district, the committee unanimously agreed that the Council offer no opposition to the company's obtaining the provisional order. The maximum price chargeable by the company was set at 8d. per unit, which, the committee were told, was equivalent to 4s. per thousand feet of gas. Mr. Bownass said the committee went into the matter very carefully as regarded the question of giving consent, and it appeared that in the provisional order the interests of the public were very carefully protected throughout. The only point of importance in the order was the purchase clause, giving local authorities power to purchase within 42 years on a 5 per cent. basis. The Council agreed to consent to the provisional order.

Cheltenham.—A letter has been read at a meeting of the Town Council from Messrs. Griffiths, Ryland, and Co., on behalf of Mr. Reed Muller, of Staverton. It alleged that a horse belonging to Mr. Muller had fallen into an excavation made in the roadway in Lower High-street by the Corporation men for purposes alleged to be connected with the electric light, and sustained bad injuries to his knees. Ten pounds compensation was claimed. A claim was also made by Mr. J. R. Higgins for 15s. damage to boxes, etc., at 108, High-street, owing to a service pipe being cut by one of the workmen employed in the trench. Mr. Lionel Millns, 20, All Saints'-road, claimed damages through falling into an exposed excavation near the end of North-street, and injuring his thumb and ruining a pair of dress trousers in the tar in the trench. It was resolved to offer Mr. Muller £5 without prejudice, to pay Mr. Higgins the amount of his claim, but to admit no liability in the case of Mr. Millns's accident.

Liverpool.—A most important decision was arrived at on Monday by the Lighting Committee of the Corporation, over which Alderman F. Smith presided. In view of the action of the City Council last week empowering the committee to enter into negotiations for the purchase of the Liverpool Electric Supply Company's undertaking within the city, various matters appertaining to the lighting of the city were under discussion, but a new departure in the consideration of the question was initiated by a proposal that the Corporation should make application to the Board of Trade for a license to enable them to light the streets of the city by electric light, and, if need be, to supply electricity in the same way as now being done by the Liverpool Electric Supply Company. This proposition gave rise to an animated debate, and it was only adopted by four votes to three, the division being—for: Alderman F. Smith, Alderman Hawley, Councillor Brownbill, and Councillor Topp; against: Councillor W. J. Burgess, Councillor Austin Taylor, and Councillor Petrie.

City of London Company's Revenue.—Mr. J. Cecil Bull, manager and secretary of the City of London Electric Lighting Company, Limited, has sent us some figures concerning the Company's revenue during the quarter ended December 31, 1894. The receipts from the sale of current for public lighting in that period were £3,181. 3s. 2d., as compared with £3,105. 4s. 9d. in the corresponding quarter of 1893; and from private lighting

Digitized by Google

£26,052. 5s. 3d., as against £13,091. 9s. 11d. in the same quarter of 1893. The estimated revenue from other sources is £404, as compared with £450. It will be seen that the total increase during the last three months of 1894 shows an increase over the corresponding quarter of 1893 of £12 990 13s. 9d. Another interesting item is that the equivalent of 135,460 8-c.p. lamps were connected to the mains on December 26, 1894, being an increase of 21,429 during the quarter; whilst the number of lamps connected on December 26, 1893, was 65,341, the increase in that quarter being 11,896.

Ventilating and Warming Appliances.—A new catalogue is being issued by Messrs. Baird, Thompson, and Co., Limited, of Charlton Engineering Works, Islington, of ventilating, warming, drying, and other appliances of which they make a speciality. This new edition contains a large number of new and artistic designs suitable for all classes and styles of architecture. The company are now enabled to turn out their appliances more expeditiously and at a greater saving of cost, in consequence of which reduction has been made in prices. The following are some specialities: ventilators (automatic and mechanical), extractors, and inlets; electric ventilators for all purposes, air propellers, belt driven or with high-speed engine; water motor, compressed-air motor, also by electricity; compressed-air system of ventilation, warming, and drying, also cooling, water-spray system of ventilating and cooling, smoke flue ventilators, chimney cowls, systems of heating by steam, hot water, and hot air, and the Plenum system of combined ventilating and warming for all classes of buildings.

Birmingham Central Tramways Company.—The petition of this Company for authority to reduce capital has come before Mr. Justice Stirling. Counsel stated that the Company was formed in 1881. Its paid-up share capital was £488,000—£388,000 in ordinary £10 shares and £100,000 in 5 per cent. preference shares. Its difficulties had arisen in consequence of taking over concessions and leases of other tramways outside the borough. These had proved unremunerative, and had been abandoned; but the amount of capital lost or unrepresented by available assets was now set down at £194,000, or half the ordinary capital paid up. This the Company proposed to strike off by reducing the value of the ordinary shares from £10 to £5. There were debentures to the amount of £162,000, and in Chambers the judge had not required that notice should be given to them. Mr. Justice Stirling said he would require the Company to advertise the reduction, and to give notice to the Birmingham Corporation and some other of the debenture-holders. If, within a week after such notice, no objections were raised, the order asked for would be made.

Southport.—A meeting of the Electricity Committee of the Town Council was held on December 18, when they resolved that a low-tension cable be laid down in Portland-street from Coronation-walk corner to Nelson-street; also that an order be given for 10 10-ampere meters. It was resolved that the Watch and Public Halls Committee be informed that the failure of the lights in the Council chamber recently was owing to insufficient fuses on the consumers' side of the meter, for which the Electricity Committee were in no way responsible. At a meeting of the Town Council, Councillor Hesford proposed and Councillor Todd seconded the adoption of the minutes. The Mayor, referring to the erection of the new chimney, said he hoped the greatest care would be taken in carrying out that work, and that the best materials would be used throughout. Councillor Hesford stated that they had specified that the chimney should be sufficient for the requirements of 10 boilers working at the same time, that it should withstand a wind pressure of 90lb. to the square foot, and that the foundations should be to the satisfaction of the committee. The motion was carried.

Dewsbury.—The minutes of the Lighting and Water Committee of the Town Council, dated December 17, stated that a letter received from Messrs. Crompton and Co. suggested that the Corporation should have a supply of carbons for use in the new arc lamps. The town clerk reported that, after seeing the chairman and the electrician, he had given Messrs. Crompton and Co. an order for the supply of the 650 pairs of carbon, and his action was ratified. The resolution referring to workmen required at the electric lighting station was reconsidered. The electrician laid before the committee a report upon the duties of the several workmen engaged, and recommended that at present at least not one member of the staff could safely be dispensed with. It was resolved that, after reconsideration of the matter, the committee do still adhere to their resolution of November 19. Alderman Robinson, in moving the confirmation of the minutes at a meeting of the Town Council, said that every member of the committee was present when the matter was referred back to the committee for reconsideration relating to the men employed at the electric lighting station. The electrical engineer was present, and he could not at present see his way to curtail the staff previously recommended, but gave the committee an assurance that if it was necessary to diminish the staff as time proceeded he would do so. Councillor Archer seconded the motion, and it was carried.

Cardiff.—On Monday, at a meeting of the Borough Council, Councillor Good moved, "That this Council herewith resolves that a special committee be appointed to make a searching and impartial investigation into the cause or causes of the late extraordinary and vexatious delay in completing the electric lighting of the town, and as contrary to the statement made both by the electrical engineer and the borough surveyor, according to the minutes of September 19, 1893, that the said lighting should be carried into effect either in December, 1893, or January, 1894." Councillor Morgan Morgan seconded the motion, as he explained, so as to put the matter in order. Councillor Beavan denounced the motion as a reflection upon the Lighting Committee. The Mayor, as a member of the Lighting Committee, asked the Council if they supposed for a moment that the members of the Lighting Committee would continue to act if the resolution was passed? For his own part, as chairman of the Lighting Committee, he would not think for a moment of acting any further on the committee if the resolution was passed. Why didn't they ask for information? Councillor Jenkins asked if the borough engineer could inform the Council whether they had had to pay for the lighting experiments made at the station in the shape of wages to the men employed there, and with regard to the consumption of coal. The Mayor said that the men employed at the station were employed there permanently. Latterly, experiments had been made during the period in which the street lamps had been lighted, besides which they had 39 private customers. They had afforded light to these customers and had used their coal for this purpose, and for this they were paid. Applications for the light were coming in fairly well now. He was pleased to see from the returns at Portsmouth that they in Cardiff were in exactly the same position with regard to plant, rectifiers etc. At Portsmouth they had only had the light going six months, and expected to declare a dividend of 5 per cent. He admitted that there had been considerable delay in getting the electric light in operation in Cardiff, but pointed out that they had been 18 months looking for a site, and they were afterwards delayed, owing to a strike, in getting their machinery. The motion was then put to the meeting and lost by a large majority.

Electric Construction Company, Limited.—This Company, who report that the past year has been a very busy one with them, state that the reconstruction of the Company took place during the latter part of 1893, that during 1894 the staff of the Company and the business generally have been completely reorganised, and that Mr. Parker left the Company in April last, and Mr. Blackburn was appointed chief engineer. Since then the re-establishment of the business has proceeded satisfactorily. Mr. Garcke retired from the position of managing director at the end of the year. During the period of his connection with the Company the reconstruction and reorganisation above referred to have been carried out, and the Company is now in smooth waters. The business of the Company has steadily increased, and we are informed that the orders executed during the past half-year have been of an amount equal, if not greater, to that of any previous half-year in the Company's history. The central-station work on hand during the year has included complete electrical equipments for the Wolverhampton Corporation and for the united parish of St. James and St. John, Clerkenwell; dynamos and accessories for the lighting stations of Halifax, Crystal Palace District, Chelsea, Liverpool, Stafford, Aberdeen, Nottingham, etc.; and a large number of motor generators, both continuous current and alternating current, for various stations, including Brighton Corporation, Oxford, etc. Traction work has included the extensions of the Liverpool Overhead Railway, complete electrical equipment of the Madras electric tramways, and electric locomotives for South Africa. In general dynamo, motor, and switch work the Company has been exceedingly busy, an unprecedented number of machines for private firms having been delivered during the autumn. Several large orders for power transmission, mining, and pumping plant have also been executed. The orders at present in hand are sufficient to keep the shops fully employed for several months, and include the equipment for Clerkenwell, alternators and transformers for the St. Pancras Vestry, six 65-kilowatt transformers for Birmingham, plant for South Africa, dynamos for the War Office, motor transformers for Manchester and Birmingham, lighting plant for China, etc., in addition to a large number of general orders.

Halifax.—On Thursday night last week, in celebration of the completion of the Corporation electric light works, the contractors, the workmen who have been employed on the undertaking, and others had dinner together at the Talbot Assembly-room. The company numbered about 170. Alderman J. Brook, as chairman of the Gas and Electric Light Committee of the Town Council, presided, and the other members of the committee present were the Mayor (Alderman M. Booth), Alderman Patchett, Alderman Brear, Councillors T. Greenwood, R. Hodgson, W. H. Spencer, D. Woodhead, Rushworth, and T. Braithwaite. The gathering also included the architect (Mr. W. H. D. Horsfall), Mr. T. P. Wilmshurst (electrical engineer), and Mr Holgate (gasworks manager). Councillor T. Greenwood proposed "Success to the Electricity Works." He remarked, in doing so, that he considered they had an installation that was second to none in the world. It was in 1892 that the then Mayor, the late Alderman Davis, brought the question of the electric light forward, and the matter came before the Town Council as to whether they should carry out the necessary works themselves, or allow the undertaking to be transferred to a private company. The result was that they decided that the works should be municipalised. The cost of the installation at Halifax was about £6 per light. The Corporation had now applications for 3,000 16-c.p. lamps. Their full capacity was 6,000 lamps, and he felt confident that before three years were over this would be utilised to its fullest capacity. The chairman reminded the meeting that the sanction to proceed with the works was only received by the Corporation in December, 1893. That they should have had the works brought to their present position in so short a time was, he thought, exceedingly creditable to all concerned. Regarding the income, they were deriving from the present number of lights an income of fully £2,000 a year. It was not, of course, to be expected that the works would pay immediately. They had now only running capacity of 500 h.p., and they had sufficient

Digitized by Google

room, both for boilers and engines, that would give them three times that capacity, without any extension of buildings being necessary. Mr. Wilmshurst said that they had the satisfaction of knowing that they had the very best system they could possibly have. They were doing nothing experimental, but they were doing what had been done in electric light works before, where the methods they were adopting had answered successfully. Throughout they had had nothing but first-class material and first-class work, and he considered that the different contractors deserved their thanks for the heart, soul, and energy they had put into the work. No one entering the engine-room could help being struck with the solid and substantial look of the plant. In fact, it looked as if it had come to stay, and he must say that Messrs. Pollit and Wigzell, of Sowerby Bridge, deserved very great praise for the creditable show they had made in their engines.

PROVISIONAL PATENTS, 1895.

JANUARY 7.

378. **An improvement in dynamos or electric generaters by means of which a constant pressure is maintained under varying speeds.** George Edwin Fletcher, "The Homestead," Cale Green, Stockport.

396. **An improved grid for secondary battery plates.** Alfred Slatter, 7, Ridgmount-street, Bedford-square, London.

398. **Improvements in automatic telegraph instruments.** Henry Whawell, 11, Aldebert-terrace, Albert-square, Clapham, London.

432. **Improvements in electric accumulators or secondary batteries.** Eugene Ageron and Alfred Fournier, 18, Buckingham-street, Strand, London.

437. **Improvements in and connected with electric arc lamps.** John Brunswick Barton, Norfolk House, Norfolk-street, London. (William Jandus, United States.)

JANUARY 8.

480. **Improvements in electrical measuring instruments.** Edward Stanley Shoults and Gustav Binswanger, 73, St. Stephen's-road, Upton Park, London.

497. **Improvements in and relating to electric railways.** John Charles Love, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

523. **An improvement in lightning arresters.** Reginald Belfield, 28, Southampton-buildings, Chancery-lane, London. (The Westinghouse Electric and Manufacturing Company, United States.)

525. **Improvements in magnetic cut-outs.** Leonard Andrews, 166, Fleet-street, London.

527. **An improved galvanometer lamp, stand, and scale.** Henry Frederic William Burstall and James Joseph Hicks, 23, Southampton-buildings, Chancery-lane, London.

JANUARY 9.

530. **An improved electrical current reverser and testing key.** Richard Harvey Tonking, 84, Annandale-road, East Greenwich, London.

531. **Dynamo machines for producing alternating electric currents of low tension.** Arthur George Adams, 29, Storer-road, Loughborough.

541. **An improved combined electric bell and indicator.** August Eckstein and Richard Pentney Eidsforth, 45, Chapel-street, Salford, Manchester.

545. **Improvements in electrical switches.** Charles Mark Dorman and Reginald Arthur Smith, Ordsal Electrical Works, Salford, Manchester. (Complete specification.)

546. **Ignition and gas-generating body for explosive engines rendered incandescent by an electric current.** Anton Niemczik, 10, Friedrichstrasse, Berlin. (Complete specification.)

JANUARY 10.

619. **A mode of giving warning by means of electric bells of the approach of trains at level crossings on railways.** Thomas Ireland, Babworth-road, Retford, Notts.

620. **Improvements in electrical apparatus for protection against fire** William Jeffrey and Frank Taylor, 11, Queen Victoria-street, London.

632. **Improvements in galvanic or primary electric generaters.** Eugène Ageron and Alfred Fournier, 18, Buckingham-street, Strand, London.

656. **An automatic clutch-sustaining device for brackets, pedestals, or other fixed or movable supports for electric light lamp and other purposes.** John Edward Preston, 58, Lombard-street, London.

671. **Improvements in magnetic cut-outs.** Leonard Andrews, 166, Fleet-street, London.

JANUARY 11.

684. **An improvement in and relating to lamp-holders for incandescent electric lamps.** George Christopher Cannon, Engineering Works, Bellshill, Lanarkshire.

687. **An improvement in machines for transforming continuous or direct currents of electricity and for other purposes.** George Cheffey-James and Harry Percy Ward, 25, Thoresby-road, Hillsbro', Sheffield.

712. **Process for the electrolytic extraction of nickel and cobalt from ferruginous raw materials.** Ludwig Münzing, 433, Strand, London.

736. **Electric alarm detector and valve for chlorine gas.** Richard William Hill, 97, Newgate-street, London.

737. **Production of aluminium and generator of electricity.** Richard William Hill, 97, Newgate-street, London.

JANUARY 12.

807. **A process for the electrolytic decomposition of alkaline chlorides.** Wilhelm Siepermann and Hermann Riegermann, 4, South-street, Finsbury, London.

816. **Production of gaseous ammonia by electricity.** Richard William Hill, 97, Newgate-street. London.

817. **Production of nitric acid by electricity.** Richard William Hill, 97, Newgate-street, London.

818 **Improvements in phonographs.** Vincenz Lahola and Adol Sachs, 23, Southampton-buildings, Chancery-lane, London.

825. **Improvements in arc electric lamps.** John James Mann and Lucien Hermand, 47, Lincoln's-inn-fields, London.

831. **Improvements in and relating to electric arc lamps.** Robert Cornelius Quin and Benjamin Symmons, 124, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1888.

11898. **Indicating strength of an electric current.** Shallenberger. (Second edition.)

1891.

4583. **Electric supply meters.** Perry. (Second edition.)

1894.

3476. **Electric bells.** Little.

3667. **Telegraphic apparatus.** Phonophore Company and Smith.

4691. **Connecting and disconnecting electrical circuits.** Lundberg and others.

7121. **Electric lighting apparatus for railway cars, etc.** Biddle and Kennedy.

22192. **Electric exploder.** Siemens Bros. and Co. and Schloemer.

22453. **Insulated electric conductors.** Robinson.

NOTES.

Calendar.—A calendar for 1895 has reached us from Mr. J. H. Sankey, of Iron Bridge and Essex Wharves, Canning Town, E.

Electric Drills.—An electric drill has been employed in the drilling of the bottom plates of the "Talbot" at Devonport Dockyard.

Physical Society.—The date given in our last issue of the meeting of this society should have been January 11, 1895, and not November 11, 1894.

Telephony.—On Wednesday Llanwrda, Pumpsaint, and Melin Rhos (Farmers) were connected by telephone to the Post-Office system of telegraphs.

Electric Lighting at Buluwayo.—It is stated that arrangements have been made for a telephone exchange and the installation of electric light at Buluwayo.

Australian Telegraphy.—Telegraphic communication with the Antipodes has been suspended for some days owing to damage to the land lines on the other side.

Strike.—A strike of electric tramway employés is taking place at Brooklyn, New York. A full report of the proceedings will doubtless be found in our contemporaries.

Glasgow Tramways.—The Tramway Committee of the Town Council have declined a proposal submitted by a private firm offering to work several of the lines by electricity.

Finsbury Park and City Railway.—The Examiner on Standing Orders passed on Wednesday the Bill for constructing an electric railway from Finsbury Park to Moorgate-street.

Lecture.—Mr. W. Perren Maycock, M.I.E.E., gave on Saturday evening last a lecture on "Electricity" at the Thornton Heath Polytechnic, Croydon. The lecture was illustrated by experiments.

Electro-Harmonic Society.—As mentioned in our last issue, a smoking concert of this society will be held this (Friday) evening at the St. James's Hall Restaurant. The programme was given a week ago.

Explosion.—An explosion occurred on Friday afternoon at the bottom of St. James's-street, S.W. It was accompanied by a report, and the iron lid of a manhole was blown in the air and fell on the footpath.

Proposed Teaching University.—Lord Rosebery received on Tuesday deputations for and against the proposed teaching university for London. He expressed himself in favour of the report of the Gresham Commission.

Telegraphy in the East.—Preliminary work has been commenced in connection with the extension of the telegraph lines from Burmah to China. A telegraph line connecting Darya Khan with Dera Ismail Khan is to be constructed.

Telegraphy in Madagascar.—The Hovas, a *Times* correspondent says, are constructing a telegraph line to Vatomandry, in order to secure the direct transmission of their telegrams to London without the risk of their being intercepted by the French.

Research.—The Executive Committee of the City and Guilds of London Institute have awarded the first Salters' Company's Research Fellowship for the encouragement of higher research in chemistry, in its relation to manufactures, to Mr. Martin O. Foster, Ph.D., F.C.S.

Acton Tramways.—A public meeting has been held in regard to the proposed tramway extension to Acton-hill. An address was delivered by Mr. J. Clifton Robinson, the managing director of the United Tramways Company, who made special reference to the point of electric traction.

City and South London Railway.—The Examiners on Standing Orders of the House of Commons on Monday passed the City and South London Railway Bill to extend the time for the completion of the underground electric railway authorised in 1890 and to raise £30,000 additional capital.

Light Railways.—The Committee on Light Railways appointed at the Board of Trade conference on the 6th of last month held their final meeting on Wednesday, Sir Bernhard Samuelson being in the chair, when the report to be made to the conference at its next meeting on the 31st inst. was finally agreed upon.

Society of Arts.—The third Cantor lecture on "The Arc Light," by Prof. Silvanus P. Thompson, D.Sc., F.R.S., will be delivered on Monday. It will deal with arc lamp mechanism, the requirements to be met and methods of fulfilling them, alternate-current lamps, special lamps, qualities of carbons, and accessories.

Personal.—The Electrical Company, Limited, of Charing Cross-road, inform us that they have obtained the services of Mr. J. Stottner, one of the engineers from the Allgemeine Elektricitäts-Gesellschaft, of Berlin, who represented this influential firm at the Chicago Exhibition. The Electrical Company anticipate doing a large business in the transmission of power department, which is being managed by this gentleman.

Institution of Junior Engineers.—The tenth anniversary of the Institution of Junior Engineers, now numbering 400 members, is to be celebrated by a dinner the Westminster Palace Hotel on Saturday. The chair will be taken by the president, Mr. A. Siemens, who will be supported by Major-General Webber, C.B., Sir A. K. Rollit, M.P., and Profs. W. E. Ayrton, J. A. Ewing, George Forbes, and John Perry, F.F.R.S.

Chloride Storage Batteries.—The Chloride Electrical Storage Syndicate, Limited, inform us that the recent litigation or disputes between themselves and the Electrical Power Storage Company, Limited, and the Electric Construction Company, Limited, have been settled on mutually satisfactory terms, and that they continue to make and sell their batteries as hitherto. We are glad to publish this item. No doubt the consolidation of storage battery interests in the United States, to which we referred a few week ago, has had something to do with bringing about this satisfactory result.

Wear of Trolley Wires.—A statement was recently made in the *Elektrotechnische Zeitschrift* to the effect that a particularly strong wear of the trolley wires in the case of electric tramways took place through electrolysis in damp weather if those conductors formed the positive wires of the system. Herr von Hefner-Alteneck now writes to that journal expressing the opinion that the wear of the trolley conductor must not be attributed to electrolysis due to moisture, but rather to sparking caused by bad contact between the trolley wheel and the trolley wire, or between the sliding collector and the conductor.

Water Power in the United States.—A plan for utilising the water power of the Susquehanna River as a means of generating electric power is about to be carried out. A certificate of incorporation has recently been granted to the Susquehanna River Electric Company, and work is to be commenced as soon as the spring freshets are over. It is proposed to dam the Susquehanna River near Conowingo, Maryland, and erect a large electric power-house, similar to the one now in operation at Niagara Falls.

Digitized by Google

The power obtained in this way will be supplied to Philadelphia, Wilmington, and Baltimore, and other intermediate points. It is expected that it will be used extensively in operating street railways and electric light plants.

Chesterfield and Midland Counties Institution of Engineers.—The next general meeting of the members of the institution (Mr. William Spencer, president) will be held in Leicester, in the Mayor's Parlour at the Town Hall, on Saturday, the 26th inst., at 2.30 p.m. The following papers will be open for discussion: "The Support of Buildings," by Mr. Wm. Spencer, F.G.S.; "The Use of Expansion Gear as applied to Colliery Engines," by Mr. M. Deacon; "Reports of the Royal Commission on Explosions from Coal Dust in Mines," and other papers on the subject; "Report of the Flameless Explosives Committee of the North of England Institute—Part I., Air and Combustible Gases," by Mr. A. C. Kayll; "An Underground Endless Rope at the Moston Colliery, Manchester," by Mr. H. Richardson Hewitt.

Electrical Fittings and Glass Ware.—Almost every kind of fitting for any particular purpose will be found in the new and illustrated list of fittings issued by the Electrical Company, Limited, of 122 and 124, Charing Cross-road, W.C. Polished brass electroliers occupy the first few pages, and the designs of these fittings and those on other pages are excellent in every way. The requirements of those who own or run billiard tables are amply fulfilled, the only pity being that the merits and advantages of electric lighting for billiard-rooms have not yet been fully appreciated. The list next deals with brackets and standards, and special designs in wrought-iron electroliers. Ceiling lights, counterweights, and cut-glass pendants, simple and fancy brackets, both in brass and wrought iron, figures, ship fittings, and fancy and cut-glass shades, conclude an interesting catalogue.

Mountain Railways.—It is of course not to be expected that the Institution of Civil Engineers, as the leading organisation in the engineering world, would be unable to get at the real facts of any problems or questions discussed at its meetings. Amongst so many engineers of repute the best methods and principles must soon come to the surface, and this was noticeable at the last meeting of the institution on Tuesday. The subject of the evening was that of "Mountain Railways," being a continuation of the discussion upon three papers read recently. Strong advocacy of electric traction for such lines was evidenced by members well qualified to speak on the subject, one going so far as to say that electrical working could be effected for half the cost of steam traction, owing, perhaps, very largely to the fact that water power is in nearly all cases of mountain lines both closely adjacent and readily applicable.

Phosphorescence and Photographic Action.—A discourse on "Phosphorescence and Photographic Action at the Temperature of Boiling Liquid Air," was given by Prof. Dewar before the Royal Institution on Friday. The lecturer showed experiments to prove that bodies which at ordinary temperatures are very faintly, if at all, phosphorescent glow very brightly if, after being cooled to the temperature of boiling liquid air, they are stimulated in the light of an electric lamp. Among the substances he experimented upon were cotton-wool, feathers, flowers, egg shells, quinine, acetic acid, and some of the complex platino-cyanides, the latter giving very brilliant effects. He proved experimentally that the stimulating power of the electric lamp lies chiefly, if not altogether, in its ultra-violet rays, and he showed the curious fact that the luminous and heat rays are able to dissipate the luminosity of a phosphorescing body in those parts upon which they have fallen. The latter part of the lecture was devoted to showing how greatly photographic action is diminished at exceedingly low temperatures—even to the extent of 80 per cent.

Shot-Firing by Electricity.—An interesting and well-illustrated pamphlet dealing with electric shot-firing has been issued by Nobel's Explosives Company, Limited, of Glasgow. This subject, to which we may refer again in a future issue, is treated in the pamphlet for the guidance of those engaged in the sinking of shafts, tunnelling, mining, and quarrying operations. One of the noteworthy points is quotations from various inspectors of coal mines, either recommending the adoption of electric shot-firing or speaking in high terms of the satisfaction which this method has already afforded. Apart from this, the report of the Royal Commission on Explosions from Coal Dust in Mines is mentioned as advocating the abolition of blasting-powder in such mines and the substitution of high explosives of the flameless type in conjunction with electric fuses. The pamphlet deserves the consideration of mine owners, civil engineers, and contractors.

City and Guilds of London Institute.—The act of distributing the diplomas, prizes, and certificates gained during the past year by the students at the colleges and schools founded and maintained by the City and Guilds of London Institute, was performed a week ago at the Fishmongers' Hall by the Marquis of Lorne. Among those present were Sir Evelyn Wood, V.C. (the prime warden of the company), the Wardens, Sir F. Bramwell, Sir Frederick Abel, Mr. E. L. Beckwith, Sir Owen Roberts, Sir Walter Prideaux, Dr. William Anderson, Mr. H. Rokeby Price, Prof. Henrici, Prof. Armstrong, Prof. Ayrton, Prof. Perry, Prof. Meldola; the Masters of the Mercers', Carpenters', Cutlers', and Waxchandlers' Companies; Prof. Unwin, Prof. Silvanus Thompson, Mr. J. C. L. Sparkes, Sir Philip Magnus, and Mr. J. Wrench Towse. After distributing the awards, the Marquis of Lorne said that technical education had now spread almost all over the country, and first and foremost among those who had helped the movement were the city guilds of London. He thought it was a question whether, this stage having now been reached, the Government should not come forward a little, not so much to promote, but to sort and order.

Distribution Concessions.—Animosity between gas and electric light does not appear to be confined in any way to the pages of English gas journals or even to this country at large. Several towns in France have discovered that they are in the very unpleasant position of being pledged to the gas interests so far as any system of underground distribution (or "canalisation," as they call it) is concerned, whilst they feel anxious to avail themselves of the enormous advantages offered by electric lighting. This state of affairs is now existing at Saint-Lô, and also at Cherbourg: and suggestions have already been made that the simplest way out of the difficulty is to string up overhead wires for the electric light service. Such a remedy for a harmful monopoly is, of course, obvious, but the municipal authorities of the above-mentioned towns are naturally hesitating to permit the use of overhead wires, not merely on technical grounds, but also because at Montauban (where similar conditions prevailed and where an overhead service was erected by permission) the local authorities have been condemned in heavy costs and penalties at the instance of the gas company. The matter has been taken to appeal, but meanwhile no movement can be wisely proposed.

Electric Lighting in Brussels.—We are glad to learn that the electric light in this town is now becoming

Digitized by Google

widely adopted, thus necessitating an increase of the plant at the central station. An order for a third unit has been placed with the India Rubber, Gutta Percha, and Telegraph Works Company, of Silvertown, and it is expected that this will be erected early next month. Each unit is composed of one 600-h.p. slow-speed compound condensing engine and two continuous-current low-pressure dynamos, the distribution being on the three-wire system. The boiler plant is also being extended to meet this addition of machinery. The demand for light in the upper part of the town has exceeded expectations. It has therefore been decided to erect there an independent station, and the same company, acting as general contractors to the town, have been instructed to supply and erect the necessary plant, consisting of two 130-h.p. gas-engines, dynamos, cables, switchboard, etc., to meet immediate requirements. This satisfactory progress is no doubt due to the fact that the returns for the year's working already show a profit, although it will be remembered that the central station has only been in operation for little more than one year.

Development of Electric Railways. — Lord Kelvin distributed on Friday evening the prizes to the successful students at the Mechanics' Institute, Crewe. In the course of his address, Lord Kelvin emphasised the great value of technical training, not only because it helped young men to earn a livelihood, but for the pleasure and interest it would give them in their work. He said that in going through the great works at Crewe that day he had seen things which he should never forget. He was much struck with the great electrical developments which were going on. He himself took an intense interest in electricity, and it had been great pleasure to him to see electrical science become a great auxiliary in the work of mankind. He did not suggest it as probable, but it was possible, and it was a subject for enquiry and consideration, that dynamos might supersede steam in the working of their trains. Were that to come to pass, he did not think, from what he had seen, that the occupation of Mr. Webb or of Crewe workmen would be gone. The motto of Crewe was "Never Behind," and he did not think they would be behind in any such development. Mr. J. W. Webb, replying to Lord Kelvin's remark, said that if ever the London and North-Western Railway Company wanted a train to run by electricity they had only to give instructions, and he would undertake that it should be ready in two months.

Transformer-Chambers.—The *Journal of Gas Lighting* has climbed down and given in to the inevitable. This is what it says in regard to transformer-chambers: "The electric lighting companies of the Metropolis are to have their transformer-chambers under the streets, after all, provided these accommodation works are properly designed and constructed. We are not at all desirous of seeing the electricians hampered in their work by the insistance of the highway authorities on superfluous and pedantic restrictions ostensibly conceived in the interest of the public safety. At the same time there must be no question as to the obligation of the electricians to respect the prior and continuing rights of other users of the subsoil of the public streets. Naturally enough, the electricians exhibit a desire to throw upon other people's shoulders the blame of all street troubles connected with their plant and performances, and this is not precisely the way to make friends of those who must perforce be their neighbours. The gas companies bear them no malice, however, and are not even disposed to resent the petulant complainings of those who are without their experience in highway business; so that there is not likely to be unnecessary protesting on the part of the gas interests in regard to placing street transformer-chambers, but every instance will be dealt with strictly on its merits." "Prior and continuing rights of other users" is good.

Cooking by Electricity.—A description of Miss Fairclough's school of electrical cookery is given in *Black and White* of the 12th inst. Three good illustrations are shown of the apparatus at work and the messenger carrying out luncheons. The school was recently fitted up by Messrs. Crompton and Co., and during the few months it has been at work it has been very successful. The interviewer states that "the table (on which some of the apparatus was working) was an ordinary one of unpainted wood. Miss Fairclough stood behind it rolling pastry, while in front in a neat little row were six cooking utensils. All were of bright and shining copper and steel, from the kettle to the fluted 'griller,' and they simply stood on the table without any fire or apparent signs of heat. Yet there on the griller was a chop cooking gaily away 'with an independent air'; in the kettle water was boiling; on the hot-plate scones were toasting; in a frying-pan potatoes were frying; while two little pots were occupied by stewing bird and simmering jam. I noticed, too, that a bowl of chrysanthemums was not in the slightest degree disturbed by the neighbourhood of the kettle. The ovens, though not so startling in appearance, were soon proved to my satisfaction to be equally delightful. Each one contains six shelves, which admit of an infinite variety of roastings and bakings going on at the same time, and as the ovens heated by electricity retain their warmth for an almost incredible time after the electric current has been removed, their many advantages need no recounting. I pondered many things, and finally concluded that could all kitchens be made as ideal as Miss Fairclough's electrically-heated one, even the cook might find a chance to become a 'new woman.'"

Parker's Continuous-Current Dynamos.—In our issue of the 11th inst. we described some of the features of the new design of continuous-current dynamo introduced by Messrs. Thomas Parker, Limited, of Wolverhampton. The company have now sent us a copy of their illustrated catalogue of these machines, the special features of which, it will be remembered, are the use of hinged pole-pieces so that the armature can be readily examined and taken out by a vertical lift, and the employment of the Eickemeyer method of winding the armature. It may be as well to recall the fact that this system of winding the armature ensures perfect insulation and electrical and mechanical balance, every coil on an armature consisting of exactly the same length of wire, without any soldered joints. The coils are wound separately on formers thoroughly insulated, and afterwards threaded on to the armature core; they can easily be removed, and a damaged one can be replaced by another without entirely rewinding the armature. There is no difficulty by the use of the Eickemeyer system of winding in constructing dynamos at any E.M.F. up to 2,000 volts. The list gives details of machines built for giving voltages ranging from 52, 70, 105, 140, 210, to 525 volts. The total bearing surface of the dynamos is at least six times the diameter of the shaft. The bearings are lined with a special mixture of white metal, and each is provided with an oil well and ring, giving a continuous lubrication. After passing along the bearings the oil is thrown off by grooves in the shaft into chambers at the ends of the bearings, from which it is conducted back into the oil-well. The machines can be operated equally well as motors or as dynamos.

The Arc Lamp.—The second Cantor lecture on this subject was delivered on Monday by Prof. Silvanus P. Thompson at the Society of Arts. The lecturer discussed the optics of the electric arc. He stated that most of the

Digitized by Google

total light is given off from the crater, less than 10 per cent. coming from the peak. The crater may be regarded as a flat self-luminous area. If it could be seen in such a way that the peak never came between it and the eye, it would give the greatest light when looked at perpendicularly and the least when the line of vision was horizontal with its surface. But the shadow of the peak has to be reckoned with, and it is found that the light given off is directly proportional to the area of crater actually exposed to view, being greatest at an angle of 40deg. or 50deg. In the middle of the crater there may sometimes be discovered with the unaided eye a nebulous patch, rather whiter than the rest, which seems to be in motion. By the use of appropriate artificial means this patch may be seen as a comma-shaped object which rotates round the crater at very varying speeds, and not always in the same direction. It is a question whether this is a true physical rotation of the flame or only an optical effect. As to the efficiency of the arc regarded as a means of transforming energy into light the lecturer said that of all the rays given off by it only 20 or 25 per cent. are visible to the eye, the rest of the energy consumed being transformed into heat. He then showed an arc formed by an alternate current, and pointed out that the light from it is more equably distributed than that from the continuous-current arc. He thought it absurd to suppose there would be any difference in efficiency between the two, if the same amount of energy were consumed under equal conditions.

Terrestrial Magnetism.—A paper on this subject was presented to the Royal Geographical Society on Tuesday by Prof. A. W. Rücker, F.R.S. In the course of the paper the author stated that about 50 years ago the science of terrestrial magnetism attracted general attention, and then the interest felt in it waned. Of late, however, throughout Europe and the United States, the magnetic state of the earth has been studied with a minute accuracy never before attained. The result was that new problems had been suggested, in the solution of which travellers could do much. Dr. Thorpe and himself, in the survey of the United Kingdom, had determined the magnetic elements at about 860 places. This made the magnetic survey of this country the most complete and detailed that had ever been accomplished. The results proved that, even when the surface soil was non-magnetic, there were lines towards which the magnet was attracted. This effect was chiefly due to concealed masses of magnetic rocks. In this country there was no relation between the abnormal behaviour of the needle and the distribution of rocks of later date than the carboniferous period. In the case of the older rocks there was an unquestionable, though somewhat irregular, connection between regions of geological upheaval and lines to which the north pole of the magnet was attracted. The fact that the amount by which the needle pointed away from true north was continually changing, was at one time ascribed to a motion of the magnetic poles or foci. There was no evidence of any such movement during the last 40 years, and it was open to question whether it really occurred. The position of the south magnetic pole had been fixed in 1840 by Ross, but had not been redetermined. An antarctic expedition to investigate the magnetic conditions of the southern seas was needed to supply science with the facts upon which alone a theory of the magnetic constitution of the earth could be built.

Incandescent Lamps for Explosive Factories.—In the course of his concluding lecture to the Society of Arts on "Explosives and their Modern Development," Prof. Vivian B. Lewes referred to the use of incandescent lamps. He said: "It is not long since that a high authority on explosive matters regretted that there was not such a thing as an electric lamp which could be looked upon as perfectly safe for use in explosive factories or in fiery mines, and in concluding my subject to-night I should like to draw your attention to one which has been devised in order to meet these requirements, and which, having been exhaustively tested with regard to its safety, has been largely used at one of the South Metropolitan gasworks for such dangerous operations as cleaning the interior of gasholders, tanks, purifiers, etc. It consists of an incandescent lamp mounted upon the end of a short glass tube. In the middle of the tube is sealed a platinum disc in such a way as to be gastight. To the disc is attached a metal spring leading to one terminal, and the other terminal is connected to a wire which passes outside the glass tube, and is sealed into the outer enclosing glass envelope, which surrounds the whole of the lamp and half the glass tube, communication having been previously established between the interior of the tube and the outer envelope by means of a hole in the tube. In the outer half of the tube a platinum wire is inserted and adjusted in such a way that when air is forced into the outer envelope, the platinum disc is depressed and makes contact with this wire. The lamp thus made consists of two gastight divisions separated by the disc, the larger one containing the lamp, one terminal, and half length of glass tube, the other and smaller one containing the platinum wire. Air, or an inert gas, under pressure is sealed up in the outer envelope, causing the disc to be depressed, thus making contact with the wire, and enabling the current to pass. If the outer envelope be broken the air escapes, the platform disc resumes its flat condition, and contact is broken, any sparking that may arise on the rupture of the current being confined to the smaller gastight division, thus obviating any risk of igniting inflammable gaseous mixtures. Instead of introducing air under pressure in the outer envelope, a vacuum may be formed, when the connections between the disc and wire will have to be altered accordingly."

Electric Motor Work.—The electrical industry owes already some considerable amount to the new President of the Institution, but this debt is still more increased by his presidential address, and more particularly by those paragraphs wherein he points out very clearly the enormous advantage of electric motors in numerous industrial operations, not merely for giving a day load to central supply stations, and so helping to level the entire load curve, but also for securing a great economy of power to the consumer in work of a transient nature. Of course, the latter point, so far as electrical engineers are concerned, serves more especially as an outside argument to induce consumers to adopt electric power in their workshops. The question of a day load, however, appeals essentially to central-station men, and rightly merits their special consideration. In towns and cities like Birmingham, for instance, there are hundreds of workshops where electric motors might be installed with great advantage and economy, using up a large proportion of the central-station output for the whole day, and therefore helping to spread the load more evenly so as to run the central-station plant very economically. With regard to at least one staple trade of the Birmingham district (though not of course confined exclusively to the Midlands, since the first experiments have been made in London)—viz., that of cartridge manufacture—a series of valuable improvements in the machinery employed has just been completed by the Electrical Installation Company, Limited, of 64, Victoria-street, Westminster, S.W. This company was requested by the well-known gunmaker, Mr. Charles Lancaster, to arrange one of his cartridge-closing machines

Digitized by Google

for operation by an electric motor. This necessitated, or at least led to, some additional devices by means of which the entire process is carried out automatically, at a great saving of time and trouble. Average workmen can now do three times as much with the new type of electrically-driven machines as with the old form, wherein hand labour was largely used. Although, of course, the machines can be operated by steam power or any other mechanical method, it is obvious that the discontinuous use to which they are put in practical every-day service must render the employment of electricity by far the most economical method of working: and in this respect alone the Electrical Installation Company is much to be congratulated for showing its advantages. Every single instance of a new opening for useful work of electric motors will serve to spread their benefits still more widely, and central-station authorities owe a debt of gratitude to those who work in this direction.

Illuminating Hydro-Carbons.—A paper was read recently before the Society of Arts by Prof. Vivian B. Lewes dealing with the "Commercial Synthesis of Illuminating Hydro-Carbons." In the course of the paper the author said: "Whilst working with an electric furnace, and endeavouring by its aid to form an alloy of calcium from some of its compounds, Mr. T. L. Willson noticed that a mixture containing lime and powdered anthracite, under the influence of the temperature of the arc, fused down to a heavy semi-metallic mass, which having been examined and found not to be the substance sought was thrown into a bucket containing water, with the result that violent effervescence of the water marked the rapid evolution of a gas, the overwhelming odour of which enforced attention to its presence, and which, on the application of a light, burnt with a smoky but luminous flame. Investigation into the cause of this phenomenon soon showed that in a properly constructed electric furnace, finely ground up chalk or lime mixed with powdered carbon in any form, whether it were charcoal, anthracite, coke, coal, or graphite, can be fused with the formation of the compound known as calcic carbide, containing 40 parts by weight of the element calcium, the basis of lime, and 24 parts by weight of carbon, and that on the addition to this of water a double decomposition takes place, the oxygen of the water combining with the calcium of the calcic carbide to form calcic oxide or lime, whilst the hydrogen unites with the carbon of the calcic carbide to form acetylene, the cost of the gas so produced bringing it not only within the range of commercial possibilities for use *per se*, but also the building up from it of a host of other compounds, whilst the production of the calcic carbide from chalk and from any form of carbon renders us practically independent of coal and oil, and places in our hand the prime factor by which Nature in all probability produces those great underground storehouses of liquid fuel upon which the world is so largely drawing to-day. Wonderfully and intensely interesting as is the train of thought opened up by the discovery of this substance and its commercial production, the object I have in view this evening is not to discuss theoretic possibilities, but to show you the important effect which it will have in the direction of our great gas industry, and the phase of this which I wish to deal with specially is the value of acetylene, either for producing *per se* an enormously high illuminating effect or for the enrichment of low-grade coal gas. When the calcic carbide is placed in a glass flask, and water allowed to slowly drip upon it from a dropping tube, the decomposition at once commences with considerable rapidity, and the acetylene pours off in a continuous stream; as the decomposition continues, the solid mass in the flask swells up, and is eventually converted into a mass of slaked lime. For commercial purposes, the carbide will be cast direct from the electric furnace into rods or cylindrical cartridges, which, when 12in. long and 1¼in. in diameter, will weigh 1lb., and will give five cubic feet of gas."

Belfast Central Station.—The municipal station, which lies between Marquis-street and Chapel-lane, is now ready for supplying current to consumers. The station has been designed and the mains laid according to the scheme prepared by Prof. Alex. B. W. Kennedy, who has acted as consulting engineer to the Corporation. The plant comprises direct-current dynamos driven by gas-engines, the latter being worked by gas obtained from the city mains. By this means it has been possible to erect a station in the centre of the city, but occupying much less space than would have been necessary had steam-engines and boilers been employed. There are six gas-engines, each driving a dynamo by ropes. Four of the engines indicate 100 h.p. each, and two indicate 50 h.p. All the engines are double-acting and the largest are of the tandem type, in order to get a maximum of steadiness in the drive. The engines and dynamos occupy the greater part of a space 86ft. by 40ft., which forms the main engine-room. At the north end is arranged the switchboard, which carries all the regulating apparatus. In a room behind the switchboard is placed a battery of accumulators. The capacity of this battery is such that it can keep 3,000 lamps of 8 c.p. alight for one hour, or 600 lamps continuously for five hours. It will be charged from the dynamos, and once charged it can be discharged during the night and the light hours of the following day. In this way it will only be necessary, it is expected, to run the engines and dynamos for seven or eight hours daily during at least the greater part of the year. This matter of supplying light without running the engines is of importance, especially in Belfast, where, on account of the long summer days, the amount of lighting during a large part of the year is extremely small. The three-wire system has been adopted. The mains are laid underground, and for the most part they consist of bare copper strip arranged on stoneware insulators in concrete culverts. Prof. Kennedy's estimate of the cost of the scheme to the extent to which it is at present carried out, but exclusive of land, buildings, and meters, was £19,000. The plant was intended to be sufficient for keeping 6,100 lamps of 8 c.p. alight simultaneously, with ample reserve. The actual cost of the plant and mains as laid down has been considerably under the estimate. Mr. Charles C. Connor, M.P., who was chairman of committee at the initiation of the scheme, took the greatest interest in it, and it has been carried out under the present chairman, Alderman Pirrie. The specifications were drawn up by Prof. Kennedy, under whom the work has been carried out. Mr. C. Stanley Peach, of London, designed the buildiugs. Mr. V. A. H. M'Cowen was appointed electrical engineer to the Corporation in April last, and has personally superintended the carrying out of the work in the city since that time. The principal contractors were: buildings, Messrs. M'Laughlin and Harvey; engines, Messrs. Dick, Kerr, and Co.; dynamos, Messrs. Siemens Bros.; switchboard, Messrs. J. H. Holmes and Co., of Newcastle-on-Tyne; batteries, the Electrical Power Storage Company; copper strip, Messrs. Curtis and Sons, of Dublin; insulated cable, Callender's Bitumen Company; the cast-iron work, Messrs. Robert M'Laren and Co., of Glasgow; and roadwork, Messrs. Scott and Sellar, of Aberdeen.

THE PREVENTION OF EXPLOSIONS IN CONNECTION WITH UNDERGROUND MAINS.

VIEWS OF CENTRAL-STATION ENGINEERS.

One of the most important questions in connection with the supply of electrical energy from central stations—as we pointed out in this journal a few years ago, and as we have frequently insisted upon—is the subject of efficiently ventilating underground culverts and pipes, so as to avoid the contingency of explosions through the accumulation of coal gas. This question, it is scarcely necessary to mention, has now become one of, if not the most, absorbing subject of the day in central-station working. Our views on the subject have been fully borne out by the street occurrences during the past two or three years, and we are glad to have been instrumental in pointing out probable faults and suggesting remedies, the latter of which have in many cases been adopted.

Recent events have rendered it necessary to place before the electrical industry at large—and particularly central-station engineers, borough and consulting engineers, corporations who have erected electricity works, and those local authorities who propose or who are thinking of establishing such works—the exact position of underground systems in regard to the precautions taken to avoid, or at all events minimise, the possibility of explosions in connection with these systems. We accordingly invited the co-operation of central-station engineers in this matter, and our best thanks are due to them for so kindly responding to the following questions. We give below the first instalment of the replies, or rather their substance.

(1) Have you had any trouble or explosions through the accumulation of gas in conduits or pipes?

(2) If so, what method of overcoming the difficulty has been adopted or suggested?

(3) In the former case has the method been successful?

(4) Have you adopted any system or ventilation; if so, of what nature is it, and what have been the results?

(5) What do you consider to be the most practical method of preventing explosions in (*a*) conduit and (*b*) in pipe systems?

(6) Has there been any trouble through electrolysis?

(7) What system of draining the culverts has been adopted?

Bath.

Mr. G. F. METZGER, chief engineer of the Bath Electric Light Company, remarks that their mains are laid on the Callender solid system. No culverts or pipes are used, and the dangers of explosions through gas leakages and electrolysis are averted. The company have never had any trouble from these causes.

Bolton.

Mr. JOHN H. RIDER, the electrical engineer, has had no difficulty in the way of explosions. The sub-stations are ventilated, and the cast-iron pipes carrying the high-tension wires are to a certain extent ventilated therefrom. Mr. Rider opines that forced-air ventilation from the station end is the most practical, each manhole having a vent to the atmosphere. The best way is to only put down armoured cables. There are no culverts in Bolton, the sub-stations being drained through 6in. trap to sewer. Electrolysis is unknown.

Bournemouth.

Mr. H. M. SAYERS, the engineer to the Bournemouth Supply Company, observes that he has personally had no trouble through gas, although he has been in charge of underground mains for nine years in three different towns. In Bournemouth, there were several explosions of gas in pipes and junction-boxes before he took charge. Since then, and the use of concentric cables, none have occurred. Upcast ventilating tubes have been put in at some points and ventilating grids at others, but principally endeavours have been made to keep the cables up to high insulation and to hermetically seal buried fuse-boxes which might ignite explosive mixtures. The use of concentric cables and sealed fuse-boxes are probably the main causes of recent freedom from trouble. Mr. Sayers says that coal gas is sometimes smelt even near ventilators. It is doubtful, he states, whether a tall upcast pipe may not suck gas in through leaky pipe joints and loose walls and floors. In conduit systems (of which he has no personal experience) he thinks that grids flush with pavement, with catchpits, and opening into top of conduit, should prevent gas explosions; in pipes, maintenance of the insulation at a high figure. No doubt gas can be kept out by maintaining a positive air pressure in pipes, but this is expensive. With alternating currents concentric cables alone are free from risk of sparking, and then only while the outer insulation is good. There is no appreciable electrolysis with alternating currents. He has had some trouble on a three-wire direct-current system, any fault in a positive conductor resulting in its oxidation and parting. Bare-strip systems are sure to show copper salts on positive insulators sooner or later, especially if in a three or five-wire system the neutral conductor is earthed. Mr. Sayers does not believe in the possibility of explosions from electrolysis. The pipes in Bournemouth drain through the bottoms of the junction-boxes, the soil being sandy and bricks left uncemented purposely. With considerable difference of level, such as exist in many towns, any connection to the sewers is more likely to cause trouble than to prevent it.

Bradford.

Mr. S. W. BAYNES, the electrical engineer, is of opinion that explosions are due to short-circuits, and not to gas. He recalls the fact that he was the first to use and introduce bare conductors in culverts.

Burton-on-Trent.

Mr. F. L. RAMSDEN, the manager and engineer of the Corporation gas and electric light station, states that they have high and low pressure mains, in cast-iron pipes, and underground transformers. They have had no trouble with gas getting into the pipes or boxes.

Burnley.

Mr. F. THURSFIELD, the electrical engineer, reports that the Corporation have no pipes or culverts in the town.

Chelmsford.

Mr. H. B. PRICE, the electrical engineer to the Chelmsford Electric Lighting Company, Limited, states that gas has not caused any explosions, and that there has been no trouble through its presence. The system used is fairly ventilated through the iron lamp-poles and the poles which connect the overhead and underground mains. Ventilation and frequent inspection are considered to be the most practical method of preventing explosions. There has been no difficulty through electrolysis. Mr. Price further says that the Doulton casing, which the company use, keeps water out fairly if carefully laid. The floors of all their transformer pits are laid on a slope to let any water that may collect run into a well under the pavement box. These pits are frequently inspected and any water removed.

Charing Cross and Strand.

Mr. W. H. PATCHELL, chief engineer to the Charing Cross and Strand Electricity Supply Corporation, replies in the negative to the first three questions. A system of thorough and continuous ventilation and inspection has been adopted with satisfactory results. Thorough ventilation is regarded by Mr. Patchell as the most practical method of preventing explosions. With regard to drainage, Callender casings and brick-built boxes are used. Leakage is very slight; when it occurs it is baled out of a small sump. There has been no trouble through electrolysis.

Coatbridge.

Mr. FRANCIS TEAGUE, engineer and manager of the Coatbridge station, observes that no difficulty has been experienced through the accumulation of gas. Concerning ventilation, they have inserted a grating in the cover of each transformer-chamber, and thorough ventilation has been introduced. There are no culverts, but the transformer-chambers have each a trapped drain connected with main sewer. The high-tension mains are run through cast-iron pipes, P. O. pattern, which are gas and water proof, the ends of same being open at each chamber. All the

Digitized by Google

low-tension mains are filled in solid with bitumen, and have given every satisfaction. There has been no difficulty through electrolysis.

Derby.

Mr. J. E. STEWART, electrical engineer to the Corporation, reports that no explosions have taken place. The method of ventilation adopted is that of ventilating the ground, where possible, by and where arc lamp-posts occur. The best method of preventing explosions is "to charge the gas company with the expenses and damages." No trouble has been experienced through electrolysis. Short iron drain pipes 3in. in diameter are driven into the subsoil at each box, and no trouble in getting rid of water has been found.

Dewsbury.

Mr. JOHN B. MITCHELL, the Corporation electrical engineer, writes that nothing in use there is concerned by any of the questions. The system of mains used is Siemens triple concentric for feeders, whilst the distributing mains are single core. All the mains are buried in the earth; there are no conduits, and consequently there is no trouble of the kind mentioned in the queries.

Halifax.

Mr. P. WILMSHURST, the Corporation electrical engineer, has experienced no trouble through gas. Concerning the question of ventilation, he states that they make a practice of opening several draw-boxes every week, and if any trace of gas exists the boxes are left open for several hours. A system of ventilating shafts at intervals run up house-sides or lamp-posts, and dry air pumped into the conduits, if necessary, is regarded as the most practical method of avoiding explosions. A sump is fixed in each draw-box, which effectually drains the pipes and boxes. Electrolysis has not caused any trouble.

Hampstead.

Mr. R. A CHATTOCK, electrical engineer to the Vestry of Hampstead, observes that there has been no trouble or explosions caused through the accumulation of gas. Precautions are, however, taken by fitting a grating at the top of the transformer sub-stations. In this case the results have been perfectly satisfactory, no trace of gas ever being noticed in the sub-stations. Mr. Chattock considers that the most practical method of preventing explosions is to build the conduits on a slope, and put ventilated pockets, at not more than 100 yards apart, in the under side of roofing, and to efficiently plug the pipes at the entrance to each manhole, and to use no pipes larger than 5in. diameter. The system of draining consists in placing traps beneath the gratings, so as to catch water, and a sump being arranged at the bottom, to be emptied periodically.

Hanley.

Mr. GEO. H. COTTAM, the electrical engineer, says that no trouble has arisen through gas. With regard to ventilation, the transformer-chambers have 6in. inlet and 6in. outlet ventilating-pipes. Ventilation is the most practical method. All the chambers and many of the boxes have drains connecting through traps to the sewers. No difficulty has been found through electrolysis.

Lancaster.

Mr. A. S. BARNARD, the borough electrical engineer, states that there has been no trouble or explosions experienced through the accumulation of gas in connection with their mains, which are laid on the Callender-Webber system. No systematic system of ventilation has been adopted, but several vertical pipes rising out of the junction-boxes in different parts of the town, and which to a certain extent act as ventilators, have been erected. No difficulty has been found through electrolysis. With regard to drainage of the culverts, the surface water is carefully excluded, and very little trouble has been experienced. The junction-boxes are not watertight at the bottom, but are merely loose rubble. Any little water which enters the culverts soaks away into the soil from the junction-boxes.

Kingston-upon-Thames.

Mr. J. E. EDGCOME, the borough electrical engineer, informs us that they do not use conduits or pipes in the Kingston system, all the mains being concentric-armoured cables laid direct in the ground. It is therefore impossible for them to be troubled with explosions through gas of any kind being fired by electric sparks.

Leeds.

Mr. H. DICKINSON, the engineer to the Yorkshire House-to-House Electricity Company, reports that the company have had no trouble in regard to explosions. With regard to ventilation, he states that the surface boxes allow the gas to pass out through the lid, as the joint is not made watertight. The most practical method to adopt is to prevent the accumulation of gas by means of ventilation, and, if possible, in pipe systems to keep out the gas altogether. The manholes at the lowest points are connected to the main drains. No trouble has arisen through electrolysis.

Londonderry.

Mr. JOHN CHRISTIE, the resident engineer, states that no trouble has arisen through gas, the mains being armoured cables laid direct in the ground. With regard to the prevention of explosions in conduit systems, Mr. Christie considers that the most practical method is to use Doulton stoneware conduits, with manholes, treated as first suggested by Mr. Lewis at Hull.

Notting Hill.

Mr. GEO. SCHULTZ, the electrical engineer to the Notting Hill Company, says that no trouble has been experienced in regard to gas. The difficulty is overcome by lifting the covers and ventilating. No special arrangements have been adopted to ventilate the culverts. Ventilation from the lowest to the highest points of culverts and pipes is regarded by Mr. Schultz as the best method, whilst the culverts are drained into the main sewers. No trouble has been experienced through electrolysis.

Reading.

Mr. F. F. YEATMAN, the manager of the Reading Electric Supply Company, Limited, states that the mains in use are at present arranged overhead. Underground mains are, however, now being laid on the Callender system.

Southport.

Mr. ARTHUR ELLIS, the municipal electrical engineer, remarks that armoured concentric cables are used, and that consequently none of the troubles referred to in the questions take place. The cables are laid direct in the ground. The system is alternating. Where he has used pipes, etc, Mr. Ellis has generally adopted a Thwaites blower for forcing dry air throughout the system.

HIGH-TENSION CABLE TESTS.

(Communicated.)

A minor point in the general question of satisfactory cable insulation has lately been raised with regard to the proper testing of high-pressure direct-current cables—such as are employed for arc lighting and power transmission—with an E.M.F. of 2,000 volts or more. The majority of responsible makers of insulated wire and cables very rightly make a strong feature of their qualifications to supply good material by saying that all their cables are tested to, it may be, double the working voltage normally employed, so that any defects of manufacture may be found out at the works and at once remedied. This is an excellent plan so far as it goes, and should offer no difficulties in carrying out in the case of cables for alternating-current use, since any desired pressure can be obtained by means of transformers, but the proper testing of continuous-current cables would not appear quite so easy.

Is it satisfactory enough to use high-pressure *alternating* currents for the latter kind of test instead of direct currents? Yet it may be doubted whether direct currents from a dynamo at pressures of 4,000 or more volts are in regular use for continual testing of cables, for the difficulties of insulation in the machine itself are notorious. The mechanical strain in a cable used for a 2,000-volt direct current is probably not the same as that in a similar

Digitized by Google

cable used for alternating currents of like pressure, either in character or results, so far as one may judge from present knowledge, and an alternating-current temporary test of 5,000 volts may not develop faults which the continued application of a 2,000-volt direct current would find in a cable. Of course, a battery of cells—of sufficiently huge quantity—might furnish the required pressure, but the current would in such a case be only a fraction of that employed under normal working conditions, and the effect of full current in heating the cable is not to be lost sight of as a fault-developer.

Continuous-current machines capable of developing a pressure of 5,000, or even 10,000, volts are not only conceivable, but have even been constructed; and their use might advantageously be extended, not only for testing purposes, but also for experimenting upon much higher direct-current voltages than we have so far been familiar with. There *may* possibly chance to be some discoveries yet to be made in this connection, of no small value for industrial purposes.

SPARKING OF CLOSED-COIL DYNAMOS.*

BY GEORGE T. HANCHETT.

This most fruitful source of trouble and annoyance to the average station engineer is much more readily met if a knowledge of the causes and remedies is available. To some extent a closed-coil commutator requires a certain amount of care, closely akin to what in common parlance is termed "monkeying"—that is, the application of certain adjustments and combination of brushes and pressure on the commutator for no other good reason than that they stop the sparking. But it is also true that there are certain technical points which have a general application to closed-coil dynamos, and which cannot be neglected if sparkless running is to be understood.

In a closed-coil dynamo, whether drum or ring, the current approaches the brush in two directions from the two halves of the armature. This is shown in Fig. 1. In the figure are shown the commutator bars. Between every commutator bar is a loop of wire so wound around the armature core as to assist in producing E.M.F. when the armature is in motion in its field.

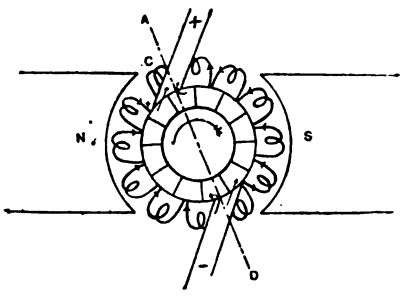

FIG. 1.

Various inventors give these loops peculiar forms and connect in different ways, but the principle is in each case the same. It is evident that the bobbins on either side of the brush are of opposite polarity, and hence both send the current toward the brush in the direction of the arrows. The coil, C, is momentarily short-circuited by the brush, and whatever the direction of its E.M.F., when delivered to the north side of the armature, the current in it will flow toward the brush. If, therefore, it is released before it gets well out of the south field, the E.M.F. in the bobbin will be in opposition to the current that is forced through it by the other bobbins, and rather than instantly establish the full current in the resisting bobbin a bright spark will occur at *x*. If we rock the brush forward until the bobbin, *c*, clears the south field, and is discharged upon the north side empty of all current, we shall have bettered matters somewhat, but since it takes time to establish current in a coil wound about iron, or, in other words, such a coil is self-inductive, a spark will still occur at *x*, although a smaller spark than in the first case. If now we rock the brush so far forward that the bobbin *c* enters the north field sufficiently to establish in it a current equal to and in the same direction as the full current in that side of the armature where it is released, there should be no spark at *x*.

In a well-designed dynamo the amount that the brush should be rocked past the neutral line is very small. The bobbin is of low resistance and the field is strong. All the E.M.F. generated is used in establishing this current in the bobbin. If the bobbin is well short-circuited, only a fraction of a volt is necessary. Hence, if a carbon or high-resistance brush is used it must have a thicker bearing surface than a low-resistance copper brush, for the commutating bobbin must be swung further into the north field before the necessary current is established therein. It is possible to secure sparklessness by short-circuiting *c* for a shorter length of time in a stronger field by rocking the thin high-resistance brush still further forward, but this tends to throw bobbins with reverse E.M.F. on the south side of the machine, which makes the machine work against itself and reduces the output. The bobbin should be short-circuited by the brush the instant it ceases to have E.M.F., and the brush should have thickness of bearing surface enough to hold it thus until the full current is established in the reverse direction. It is easy to see that the higher the resistance of the brush the more thickness of bearing surface it should have.

On general principles this is so, because the area of contact should be greater in order to transmit the main current. This may be remedied by increasing the breadth of the brush, but to properly commutate the bobbin, the brush of higher resistance should have increased thickness as well. A little consideration will show that while one set of brushes may be set correctly the other is not necessarily so. In a good bipolar machine the brushes are diametrically opposite. However, the field magnets may not establish a uniform field, and in that case diametrically opposite brushes will secure sparkless running for only one set of brushes. The other set must be set to the magnetic rather than the geometrical point of non-sparking. When the load of such a machine changes, and both brushes spark in consequence, mere rocking of the brushes will correct only one set. The other must be adjusted as before, and hence such a machine is an endless source of trouble. This fault is more liable to occur with ring than with drum armatures.

Having thus obtained an idea of the way a bobbin is reversed under the brush, we are in a position to consider the various causes of sparking and their remedies. There are several distinct kinds of sparks which appear at the brushes of a closed-coil dynamo. First, those due to an imperfectly commutated bobbin, which are of a bluish, flashy nature. These are not very destructive to the commutator. Second, those due to imperfect or insufficient contact. These are of a deep yellowish-red colour, and cut deep ruts in the commutator if allowed to continue. These two are liable to appear on a dynamo in the best of order. There are also intermittent sparks due to a local defect in the armature. To a man not familiar with the two different kinds of sparks, their distinction is a little puzzling. The spark of the improperly-commutated bobbin may be produced by rocking the brushes out of position. The second kind may be produced by applying an excess of oil to the commutator with the brushes set correctly.

The writer does not advised any prolonged experiments of this nature with a nicely polished commutator. The information may in such a case cost too dear. It is, however, important to distinguish between the sparks in order that the correct remedies may be applied. The bluish spark, due to an improperly commutated bobbin, is due only to incorrect position of the brush on the commutator. Even a thin brush, if not too thin, may be given sufficient lead to stop this sparking. If the field is unsymmetrical, as is sometimes the case, each set of brushes must be set separately at each change of load. An expert designer can often correct an unsymmetrical field by properly shaping the pole-pieces.

The other kind of sparking is due to difficulties of a mechanical nature. A rough, uneven commutator may cause the brushes to jump and spark. If the commutator

* From the *Electrical World* (New York).

Digitized by Google

is not very rough, sand-paper may be used to smooth it, but if the commutator is very rough there is no remedy but to turn it down. Oil or foreign substance sometimes causes sparking. The heat caused by the current will vaporise the oil under the brush and make a poor contact worse. The remedy is obvious. If the current is so great as to cause a heavy overload, the brushes will spark. This, of course, is not the fault of the dynamo, and efforts should be made to reduce the load. If the brushes spark intermittently, keeping step with the revolutions of the dynamo, there is a local defect in the armature. This may be due to one of the commutator bars being too high or too low, or to a loose bar. In the case of a high bar, see if it is not also loose by gently tapping it with a mallet. If it drives back with light blows, tighten the retaining rings. Never drive a bar back into position by a heavy blow, as the insulation may be damaged. In the case of a low bar tighten the commutator rings, if necessary, and turn down true. High, low, and loose bars occur only in very poorly-made commutors. It sometimes happens that the connection of a single bar has become loosened or broken, due to centrifugal force, magnetic drag, or both. This will cause an intermittent spark. If the commutator is truly round and smooth, the bar at fault may be distinguished from the fact that the bar in front is bitten away by the intermittent spark. This should be remedied at once, for that bar may become lower than the rest and a "flat" be produced.

In general, sparking will be avoided if the following suggestions are followed. The commutator should be true, smooth, well made, and of good material, and free from local defects. The brush should have a smooth, well-trimmed surface, with no frayed ends to make a loose contact. It should have sufficient area of contact to carry the current. It should have sufficient depth of contact to properly commutate the bobbin. In the case of a set of brushes this may be secured by leading one brush a little in advance of the others. This is indeed often done. Experiment is the best guide as to how much this brush should be led. The brushes should be set in the proper position on the commutator. Pressure of the brushes on the commutator should be just enough to stop the sparking and no more. The lighter the touch of the brush on the commutator consistently with no spark the better. Most closed-coil commutators run better with a very little oil. It should be applied very cautiously with a bit of felt. No commutator of this type does well with an excess of oil, and a few run better without any. Experience is here the best guide. Some manufacturers put poor insulation into their commutators. These men frown upon the use of any oil at all for obvious reasons.

INSTITUTION OF ELECTRICAL ENGINEERS, Jan. 24.

MR. R. E. B. CROMPTON (President) in the chair.

At last night's meeting of the Institution the following candidates were balloted for:

Member.—Horace F. Parshall, 38, Parliament-street, London.

Associates.—Alfred John Beaumont, 6, Scarcroft-road, York; Isaac William Chubb, 104, Royal-road, Kennington Park, S.E.; William John Corse, 17, Old Town-street, Plymouth; Rowland Edward Dixon, care of Messrs. S. Dixon and Son, electrical engineers, Leeds; John Alfred Edmondson, 23, Charles-street, Bradford; Charles Parkin Goode, 6, Lombard-street, London; R. Holiday, Acton Hall Colliery, Featherstone, near Pontefract; Frank B. Holt, 4, Leacroft-road, Derby; Alfred Edward Jackson, 26, Bramerton street, Chelsea, S.W.; John Ranald Macdonald, The Priory, Salisbury, Wilts; Oscar Albert Pilcher, 26, Percy-circus, King's Cross-road, W.C.; Harold Whiteman Woodall, "Thornlea," Fitz John's-avenue, N.W.; Frederick William Wheadon, 16, Geneva-road, Brixton, S.W.

Students.—Harry Jeffery Bellow, 85, Mostyn-road, Brixton, S.W.; Henry Herbert Bowlan, Faraday House, Charing Cross-road, W.C.; Frederick John Boyle, 48, Queen's-gate-terrace, S.W.; Upton P. Brackenbridge, 86, Chelsea-gardens, S.W.; Rowland Francis Browne, 49, Broad-street, Loughborough, Leicestershire; Walter Harvey Chapman, 3, Portland-road, Notting Hill, W.; John Dennis Coales, 4, Hawkwood-villas, Chingford; Arthur D. Constable, 129, Birchanger-road, South Norwood, S.W.; Edward Dixon, 26, Dickenson-street, Kentish Town, N.W.; Owden V. Greeves, 27, Pyrland-road, Canonbury, N.; Frank Johnston, 3, Katharine-street, Croydon; Carl Louis Lichtenberg, Finsbury Technical College, Leonard-street, E.C.; George Fletcher Malden, 56, Canning-road, Addiscombe, Surrey; Arthur B. Rayner, 68, Oakfield-road, Finsbury Park, N.; Albert Periam Pyne, 12, St. George's-terrace, Gloucester-road, S.W.; Edward Ray, 44, Palace Gardens-terrace, Kensington, S.W.; Walter Reilly, Cooper's Hill, Staines; Walter Herbert Russell, 9, Charlton Park-terrace, Old Charlton; Edgar Julius Sander, 102, Cazenove-road, Stamford Hill, N.; Frederick Charles Stephens, Durham Villa, York-road, Stepney; Lennard Carew Trevor-Roper, Bellvue, Dulwich Common, S.E.; Ernest Albert Odhams, Faraday House, Charing Cross-road, W.C.

The following paper was then read on:

The Origin and Development of the Telephone Switchboard.

BY J. E. KINGSBURY, ASSOCIATE.

The telephone itself has been the subject of various papers read before this Institution, but the same remark does not apply to apparatus which has become allied with the telephone in its commercial applications. The most important of such apparatus is the switchboard used in exchange service. It is because this subject does not appear among your records that I have treated it in the manner indicated by the title of this paper. To those who have been long engaged in telephone work such a title will not raise expectations of novel information, or suggest exhaustive treatment. To those who are not so engaged I can only hope that it may be of interest to the same extent that it is of interest to trace the development of any enterprise or apparatus.

The switchboard has been described as the brain of the telephone system. In seeking anatomical similes I hardly know whether to choose the brain, the heart, or the backbone. It is the brain in so far that it is the nerve centre, all communications going through it; it is the heart in that it is the life of the telephone system as we know it to-day; and it is certainly the backbone—of the exchange business.

The telephone, itself a marvel of simplicity, has become involved in a network of considerable complexity known as an "exchange system"—a means of intercommunication of which the switchboard is the centre-piece. The exchange system seems necessarily identified with the telephone, but it existed before the telephone was invented.

I am indebted to American sources for the information that the first idea of exchange working is to be found in a British patent granted to an inventor bearing a French name. Mr. T. D. Lockwood says: "The first idea of exchange work which to my knowledge occurs in history is found in a British patent issued as far back as February 7, 1851, to F. M. A. Dumont. This clearly describes an exchange system of dial telegraph instruments, connecting by short lines with branch central stations, which branch stations were provided with trunk lines connecting them with a principal station." Mr. Lockwood remarks that "the idea was far ahead of the times."—(Tel. Con. Rep., 1887, p. 50.)

At Newcastle the Post Office arranged a system of connecting subscribers provided with Wheatstone A B C instruments. In New York such a system was introduced in 1874 or 1875. The founder of that system was not aware that intercommunicating exchanges had previously existed. He had observed the success attending the telegraphing of stock quotations to subscribers, who each received identical information despatched from a central office, and he assumed that a like success might be obtained by furnishing information to legal firms as to the course of proceedings in the Courts. The legal firms did not take kindly to the idea, but one of them offered an alternative suggestion, intimating that a system which would enable lawyers to communicate with each other by telegraph would be worth paying for. Confirmation of this idea was obtained from others, and the result was the establishment of a telegraph exchange. As the exchange was exclusively used by legal firms, the company was called the "Law Telegraph Company." Telegraph instruments were subsequently replaced by telephones, and the particular system adopted for working the exchange became known as the "Law" system.

Notwithstanding that this telegraph exchange was already in existence at the time of the invention of the telephone in 1876, it was not until January, 1878, that the first commercial telephone exchange was started. In the meantime, Bell's invention had been greatly improved, and shortly afterwards the introduction on a commercial scale of the Edison carbon transmitter and the Blake microphone placed telephony upon such a practical basis that its progress became assured. It was the microphonic era when was commenced that activity in telephone exchange work which necessitated attention being given to switching mechanism.

In addition to the public exchange system, every large telegraph office was the centre of numerous lines, which were connected together as required by means of a switchboard. An illustration of part of a well-known telegraph switchboard shown to the meeting consists of vertical and horizontal bars, the vertical bars being the lines, the horizontal bars providing the means of connecting any one vertical line with another by

Digitized by Google

inserting plugs. The vertical lines terminate in springs resting on contacts. A telegraph instrument can be looped into circuit by a double-contact plug inserted between the spring and its contact. These springs were known to telegraphists as "spring-jacks." Those who started telephone exchanges, like all other founders of new industries, adopted in the first instance that which already existed, so far as it was within their knowledge, available for their purpose. All the first telephone switchboards have been traced by competent hands to a telegraphic origin. Hence the origin of the telephone switchboard is the telegraph switchboard, with the addition of indicators already in use for signalling purposes.

It will be remembered that telephone exchange business was started almost simultaneously in London by two different organisations—the Bell and the Edison Companies. The Edison Company had an experimental exchange at 6, Lombard-street. It was publicly opened on September 4, 1879, with 10 subscribers connected. The switchboard then used formed the subject of the first specification for a telephone switchboard in the English Patent Office (No. 3,794, September 20, 1879). The switchboard used by the Bell Company in their first exchange at 36, Coleman-street was of a different character. It is a rather curious circumstances that the two drawings of these, in addition to showing the first switchboards used simultaneously in English telephone exchanges, are also examples of two types of board—viz., plugboards and c ordboards—of which there were several varieties. The "Edison board"—as it is called here, because it was used by the Edison Company—is the upper part of the telegraph switchboard. The vertical strips are continuations of subscribers' lines; the horizontal strips are normally insulated from the vertical strips: but any vertical strip may be placed in electrical contact with any horizontal strip by placing a metal plug in the whole which is drilled at the point of intersection. Another metal plug similarly applied will place the same horizontal line into electrical connection with any other vertical line. Thus two subscribers' lines are connected together by means of a cross-bar and two metal plugs. There are no flexible cords whatever; even the speaking instrument is connected to a rigid bar. A different method is followed in the board used by the Bell Company, and consequently called here the "Bell board." The cross-bars remain, but the vertical bars are dispensed with. The subscribers' lines end in a spring-jack like the lower part of the telegraph switchboard, connections being made by means of flexible conducting cords having suitable plugs at each extremity. The one, therefore, is a plugboard, the other a cordboard; and for a while these two types provided the necessary material for the holding of opposite views amongst practical telephonists. The plugboard was preferred because it was free from the liability of broken cords, had its construction and circuits readily traceable, and also perhaps because it was generally more in accordance with previous practice in switches. The cordboard, however, had greater flexibility and possibilities of concentration.

Numerous varieties of plugboard were made, differing considerably in appearance, but having exactly the same method of working. It is not possible for me, in the time at my disposal, to describe in detail the various differences. It will suffice to say that the general idea was the same. The differences were either in construction or in the method of connecting the vertical with the horizontal bars. In some the plugs were loose, as in the one shown; in others—as in those originally used, I believe, in Manchester and Sheffield—the connecting plugs slid over a rod with notches for each horizontal bar, and were held in place by a spring clip fitting into the notch. These are differences of detail, and need not now be considered. It is of more importance to trace the methods of operation.

In the Edison board, whilst the majority of horizontal bars are free for use as connecting strips, two of them are appropriated for specific purposes. The seventh bar is connected to the operator's telephone, the twelfth bar to the earth. In order that each subscriber's line may be complete, so that the exchange may be called, the plug must be normally in contact with the earth bar. Where the fall of the indicator shutter shows that a subscriber is calling, the plug has to be taken out of the earth bar and set into the instrument bar. When the number of the subscriber required has been ascertained, the peg has to be again removed from the seventh, or instrument, bar and set into one of the other horizontal bars which may be unoccupied. The peg of the called subscriber is also removed from the earth bar and placed in contact with the horizontal bar already selected. The two subscribers' lines are then connected. No provision being made for ringing from the exchange, one subscriber calls the other. This act throws down both indicators, which the operator must replace.

In the Bell board the work is divided between two operators. One does the switching, the other the talking with the subscriber. The switching operator connects the subscriber with the table of the talking operator, who, upon learning the number required, instructs the switching operator to make the necessary connections, which he does with the flexible cords. Without detailing the various movements, it will suffice to draw attention to one point. The subscriber's line comes to a spring, and the spring rests on a contact. The contact is the earth. The plug with which connection is made removes the line from the earth, and that is one step in advance of the Edison board. A line needed to be broken and diverted. These requirements were separately met in the Edison board, whilst in the other case they were combined. In the development of telephone switchboards that is equivalent to making two blades of grass grow where one grew before.

The cordboard offered facilities in this direction which the pegboard did not. According to the Telephone Convention Report for 1883 (p. 33), plugboards were the most popular in 1881; there being amongst the companies reporting to the association 11,904 subscribers on plugboards, and 8,893 subscribers on cordboards. By 1882 the conditions were changed, cordboards having 16,799 subscribers and plugboards 12,755. By 1883 the change was shown to have some substantial foundation, the figures being 21,432 for cordboards and 12,763 for plugboards. These figures do not refer to the identical boards illustrated to the meeting, but to all varieties of their respective types. They show that the intervening period was sufficiently active and exacting to have had some influence in deciding which was the fittest type of board for survival. That type was the cordboard, and it may be desirable now to trace briefly the development of the most generally used form of cordboard for small exchanges.

For this purpose it is necessary to call your attention to a patent specification which I think may be called a classic in this branch of invention. It is dated November 29, 1879, numbered 4,903, and granted to C. E. Scribner. In the "universal jack-knife switch" there are the indicators and the individual connecting springs for the lines as in the Bell board, but arranged in distinct groups, and there are the horizontal connecting bars also. Although there are these points of similarity, there are improvements over each. In the Bell board the line comes to the indicator first, then through the spring-jack to earth. Inserting a plug into the spring-jack cuts off the earth, but the indicator remains in circuit. Scribner cuts off both drop and earth in one operation by the simple device of putting the drop the earth side of the jack, so that both subscribers' indicators are cut out of circuit instead of both remaining in. This is another step forward. The horizontal connecting strip is also improved by being turned round when engaged.

In connecting the two subscribers' lines together, two cords were used, as in the Bell board, each cord having a plug at either end, and the calling subscriber's line was connected to the revolving bar by one cord, and the same revolving bar connected to the called subscriber's line by the other cord. But, as both subscribers' indicators were cut out, some provision must be made for the reception of a disconnection signal. This switchboard brings us one more step forward in the inclusion of signalling apparatus in the connecting cords or bars at the central office, and I would invite particular attention to the way this was done, because I think that it has been overlooked by some writers on telephone subjects. To each bar an idicator was connected in derivation, one end of the coil being connected to the bar, and the other to earth. The specification says: "The earth connection of the coupling bar being through the coils of a magnet in no way interferes with the telephonic conversation"; which remark you will apply to the lines then prevalent with the electromagnet then used. The clearing-out drop was not mounted on the switchboard—there was a relay operating an audible signal; but a complete indicator is allowed for in the description. Although a clearing-out drop was connected to the central office circuit, the operator's telephone was still at the extremity of a separate cord, and needed to be plugged into or out of a spring-jack in order to be brought into or out of the subscriber's line circuit.

The circuit made up by the operator for the purpose of joining two subscribers' lines consisted of two cords and a bar. There were the operations of putting two plugs into spring-jacks and two plugs into a bar. If the two cords were permanently attached to the bar, a part of the work would be saved. If, further, the operator's telephone were to be switched into or out of the line by a key, the operations required would be more quickly performed.

The rapidly-increasing numbers in the exchanges rendered the bar system impracticable, whether of the fixed or revolving pattern. The bar therefore was discarded; the cords were lengthened, joined together, and the circuits so arranged that the ringing battery or generator, the operator's telephone, or the clearing-out drop, could be brought into use as required by the easy manipulation of keys placed in the most suitable position. This stage was reached in the switchboard now generally known as the standard switchboard. Its development dates from 1879, the germ being found in the universal jack-knife switch. The keyboard was an entirely new feature in switchboards, and was the logical result of the combination of connecting cords and plugs with clearing-out drops. The arrangement of the parts was strictly decimal—an obvious advantage hitherto neglected. Some of the keyboard circuits,

Digitized by Google

being also applicable to multiple boards, were patented here, such as in specification No. 3,116, 1883, whereby the operator's telephone is in circuit immediately a plug is inserted in a jack. This is inserted by means of the other plug of the pair resting on a plate to which the telephone is connected, and accounts for the metallic heel-piece to the plug which then came into use. This board has been greatly altered in the parts of which it is composed, but in general arrangement and in the methods of operation very little, if any, improvement has been found possible, and for small exchanges it has been extensively adopted, or imitated substantially in its original form. Sufficient thought had been bestowed upon it to enable it to assume a form based on sound principles. The board was upright, with a shelf for keys and plugs. What was needed to be seen or handled was placed in the front of the board, but nothing else. All the connecting wires were placed at the back of the board, so that they could be attended to by the mechanic without interrupting the operator. The importance of this arrangement is very apparent now.

The introduction of the standard board probably accounts for the figures which I have already referred to as indicating the change in general estimation of plug and cord boards. Although the flexibility and concentration available with cords must have led to their general adoption, it is of interest to note how the placing of the operator's telephone into the cord circuit overcame one of the principal objections to cords. The existence of a broken cord must become known to the operator in the process of making a connection, and it could therefore be laid aside for another.

Whilst the standard board remains the most effective of what may be called "simple" switchboards—that is to say, those in which a subscriber has only one spring-jack or point of access to his line—it also forms in its constructive and keyboard arrangements the foundation for the more elaborate multiple board, which, although previously invented, soon borrowed the general disposition and the simple and practical mode of operation of the standard board.

The multiple board, as originally designed, employed the Scribner "jack-knife" switch, which was never used in England, I think. It consists of a metallic frame, with a blade pivoted at one end and resting on an insulated stud at the other. There are two holes. These are for plugs—one for the instrument plug, and the other for the connecting plug. The insertion of either plug will lift the blade from the stud, and so break the earth and indicator contact. The importance of space on the front of a switchboard led to a change in the jack-knife switch at an early date. Instead of lying lengthwise across the front of the board, the blade or spring followed more after the fashion of the spring in the Bell board—*i.e.*, having its length from the rear to the front, instead of from side to side. Though entirely different in appearance and construction, the modified switch was the equivalent of the jack-knife electrically. Whilst previous springs, as in the Bell board, were operated by flat plugs, the designer of the new spring-jack retained the round plug as used by Scribner, altering the shape so that it should be retained in position by the tension of the spring. This spring-jack and plug remain in their essential features the patterns now in use. The adoption of a round instead of a flat plug may seem a small matter, but it would require a very considerable amount of calculation to estimate the aggregate saving in time and money which has resulted therefrom.

It may be of interest to state that the inventor is Mr. J. C. Warner, one of the oldest of the expert staff of the Western Electric Company. Mr. Warner designed not only the jack, but also the indicator used on these switchboards. He brought to the design of telephone apparatus a wide experience, and you will probably agree with me that he graduated in a good school. Born in London in 1822, Mr. Warner became engaged in the manufacture of electrical apparatus in the workshop in which instruments were made for Cooke and Wheatstone. Subsequently he made some apparatus for experimental use by Morse on the line between Baltimore and Washington.

Having traced the simple switchboard to the stage in which it is supplied with an indicator and a spring-jack for each line, with pairs of plugs and connecting cords in whose circuit are placed convenient keys whereby the calling generator and the operator's speaking instruments can be quickly brought into circuit with either subscriber's line, consideration may be given to the more elaborate outfits required for large exchanges. It was on such a foundation that the multiple board was practically introduced, though it was designed at a much earlier period, and was being gradually matured.

For the purpose of illustrating the prior condition of affairs, I will recall attention to the Edison board, which, as I have mentioned, was installed in 1879. About the middle of 1880, the Edison Company amalgamated with the Bell Company. Some recommendations were then made for alterations in the switching arrangements. It was suggested that the operating should be divided between talking operators and switching operators, as in the Bell board, with the difference that the subscribers' lines should be continued to the talking table. Seventy-five lines were to be assigned to one talking operator, who was to be assisted by two others as switching operators. On the fall of an indicator the talking operator would depress the key pertaining to that line, would ascertain the number required, and then instruct the switching operator to make the required connections. If it should happen to be with a subscriber in another section—say, 200 in the third section—the switching operator would fix the peg in his own board, and then go to No. 3 board, fixing there the proper peg to connect No. 200 of that board with No. 1 of his own, using therefor the special connecting strips set apart for connecting each and every board individually with the other. It was asserted that "by this means an exchange can never become unwieldy." How soon that anticipation became falsified, only those concerned with the practical work of exchanges are able to appreciate. The method of connecting separate boards by special "strips," or bars, was very much improved by "transfer" systems as they were called when applied to standard boards; but by dire experience it became evident that the rapidly growing exchanges could not be satisfactorily or economically conducted when there was only one connecting point to a subscriber's line, and when communicating conductors had to be made up by sundry operators to enable a connection to be made.

I will show you an attempt to provide a remedy. It is recorded in a United States patent (No. 252,576), which was filed January 7, 1881, and from the wording of the specification I gather that the system was in actual use. The subscribers' lines passed through a number of boards (it was on the "Law" system, and easily done). The subscribers' numbers were inscribed on a signal-board placed in a central position. These numbers could be obscured by shutters. When a subscriber was put through, the operator would instruct the attendant at the signal-board to obstruct the number. On disconnecting, the reverse instructions would be given. Before connecting a line, the operator would look at the signal-board to see if the subscriber required were disengaged. This method was crude, but none the less deserves commendation as an attempt to overcome the difficulties which were becoming apparent. It is a multiple board without a test system. I cannot claim it as a link in the chain, because, as a matter of fact, the solution of the problem had already been in the Patent Office for over a year. It is in the specification to which I have already called attention—Scribner's, November, 1879. Numerous connecting points, without some prompt and certain means of indicating whether the line were engaged or disengaged, would be a remedy worse than the disease. A triangular conversation would be likely to produce more bad blood than a triangular duel. Now, in November, 1879, the exchange system in London had just commenced. It had certainly had a longer start, and assumed somewhat larger proportions, in the United States, but even there the necessity was not so great as to give rise to the idea which this invention conveys.

The idea is really twofold—firstly, to enable one operator, whilst answering the calls of a given number of subscribers, to connect them with any other subscriber in the exchange without requiring the aid of any other operator or making up any combination circuit; secondly, to inform the operator of the condition of the line with which connection was desired—whether engaged or disengaged. The first part of the idea was attained by increasing the number of spring-jacks indefinitely according to the number of operators required to carry on the work of the exchange. The second part of the idea is really the establishment of an information bureau in connection with every line, the bureau being supplied with information automatically, and giving up its information on demand. Three ways are shown for giving this information: one is a visual signal electro-pneumatically operated; another is the provision of double connecting blocks; the third forms the foundation of the multiple-test system as practically developed. In the diagram shown to the meeting only the local, or test, circuit is shown. The jack-knife switches illustrate two subscribers on three boards. When a plug is inserted in a jack (as is supposed to be the case in the first one illustrated), a spring, insulated from the blade, and connected with one pole of a battery, is brought into contact with a stud, which is connected by a line to similar studs on every other jack pertaining to the same subscriber. Over the studs are finger keys connected with the other pole of the battery. Depressing the key will close the local circuit and operate a bell or signalling instrument if the line is engaged, otherwise not. The information required was "engaged" or "disengaged." A local circuit partially closed at one jack would be completely closed by depressing the finger key at another jack of the same line: then the line was engaged. Depressing the finger key at one jack would not close the local circuit unless some other jack of the series had a plug inserted in it: then the line was not engaged. Here was no talking between operators, no passing of calls, or making up of lines. The information was obtained as the result of testing a local circuit, and hence the term "test circuit" as applied to multiple switchboards. I believe that the invention in the exact form shown in the 1879 specification was only used in one exchange; but it was the

Digitized by Google

subject of continued experiment and study, and was being systematically developed so that it might be ready when required. At this stage it had a test circuit entirely distinct from the line, and a test key for each jack. We might reasonably expect that the development would be likely to take the form of simplification, and such was the case.

Before I relate briefly the line of that simplification, I would like to remind you that we are dealing with a comparatively early period of the telephone industry—not too early to appreciate the advantages of metallic circuit lines, as contemporary records show, but a time when the commercial side of the telephone exchange business practically settled the nature of the lines to be run, so that single lines were the rule. It is possible that some may be surprised to hear that metallic circuit multiple boards are provided for in Scribner's 1879 patent, the necessary modifications to the apparatus being clearly described so as to adapt them to metallic circuit use; the plan would not be considered satisfactory now, as only one side of the indicator is cut out. At any rate, switchboards were required to be developed for single lines, and this enabled a simplification to be proceeded with The separate test line gave way to a much more simple contrivance, which was communicated by C. E. Scribner, and patented here on June 22, 1883 (No. 3,116).

To illustrate this improvement I must again refer to the spring-jack already described in connection with standard switchboards. It consists of three parts—a frame, a spring, and a contact stud. As a standard board jack the spring is in metallic contact with the frame. To make this jack suitable for use on a multiple board it is only necessary to insulate the spring from the frame. Place a number of these jacks in a row, connect a subscriber's line with the spring of the first jack—the spring rests on the contact beneath—connect the contact with the spring on the first jack, and you thus have a line through the board which may be broken at any jack. This is the subscriber's line wire, which continues from section to section through the hammer and anvil contacts of the jacks, which contacts are mechanically sustained by the frame, though they are electrically distinct from it. If all the frames of a series of spring-jacks are connected together by another wire, you have two lines through the board—the subscriber's line and the test line. Insert a plug in any spring-jack and you break the main line, but connect together electrically the spring and the frame. In other words, the test line becomes a branch of the main line. The main line has an earth on it. Touch the frame of a jack (which is electrically a part of the test line) with a plug forming the extremity of a partial circuit, including a signalling instrument and a battery earthed at one pole, and it will be seen that you complete the test circuit if the line is engaged, and you don't complete it if the line is disengaged. The same result is attained as by the 1879 system, but by a much simpler arrangement of parts.

Another simplification was made in the apparatus for testing. The finger key contacts on each jack (1879) were so many branches from one side of a battery. Instead of having numerous branches, the same effect could be attained by having one movable branch. This was attained (1883), one separate test plug being provided for each operator. The test plug shown to the meeting is in the form of a thimble easy of application to the frame of a jack. The drawings show a bell, or buzzer, as a signal, but a "telephone" is suggested as an alternative, and it needed only a slight change to make a still further improvement by discarding the separate testing plug, making the operator's telephone the signalling instrument, and the connecting plug the testing medium. On touching the frame of a jack with the connecting plug the operator hears a click in her telephone if the line is already engaged. This method of testing by the operator arrived at the last-mentioned stage before the multiple board was put into practical operation in England, and so it remains to-day, although the electrical circuits are very different.

The early multiple-boards were very much like overgrown standard boards, the cords being below the keyboard. As then designed the cords were not long enough, and so in the Liverpool boards (the first used in England) the cords were overhead and longer.

After the Liverpool board, an important change was made in the introduction of what is variously called the "local section," or the "answering jacks." The latter terms seem preferable, since it corresponds so well to the answering plugs used with them. The Liverpool board was arranged for 200 subscribers to a section, the spring-jacks being of the Warner pattern, mounted on wood. The jacks being arranged in blocks of 100, placed in numerical order, it will be seen that, taking, for example, the first section, the 200 subscribers' jacks of that section were all at the operator's left-hand end of the board, and all three operators had to reach those two jack panels. This difficulty was met by adding yet another jack for each subscriber—the answering jack. These answering jacks were spread out along the board, so that the answering was more promptly done, and an operator had not to reach past another in responding to a call. This plan was first introduced in the multiple board shown at the Philadelphia Electrical Exhibition. There was a further modification in the design which has sometimes been called a "double-deck" arrangement. At the top of the board were the general jacks, then the clearing-out drops, then a shelf containing half the plugs—one of each pair—then the indicators, below them the answering jacks, then another shelf with the remaining plugs and the keys. This double keyboard arrangement has been retained, but the disadvantage attending the separation of the plugs became speedily apparent. Even so slight a change in the relationship of the plugs slowed down the operating, and their separation also involved a risk of using the wrong plug for completing a connection. The separation of the plugs was therefore abandoned. The plugs were both placed on the upper shelf, the clearing-out drops and the answering jacks changed places, and this arrangement of parts is still retained. The arrangement of indicators and jacks was rendered uniform in all sections—a great advantage in changing operators from one section to another.

Another problem was met in this 1884 board. Exchanges were growing larger and larger. More subscribers had to be provided for. More spring-jacks had to be placed on a section, the face of which could not be enlarged. The limitation of size in a multiple section is easily understood. It is the limit of reach of the outstretched arms. That is about 6ft. The height is a little more variable, as the reach in that direction does not interfere with other operators. If, therefore, it becomes necessary to put an increased number of units in a given area, it can only be done by reducing the size of the units. A reduction in size of parts was then made, and further reductions have since been made. So far as designs and patterns are concerned, the size has been reduced so as to attain a capacity beyond the requirements of any exchange under existing conditions.

With the reduction in size came a radical change in the method of construction. Instead of each jack being made separately and then mounted on a base, the base and the jacks were incorporated. Twenty jacks were made into a strip, which was a combination of metal springs and insulating material. This was simply a constructive change, carefully carried out so as to make no change in the method of operation; the same round plug being used, and the same bush, carefully shaped so as to make the act of testing easy and the completion of the connection quick. Although various changes in size and construction of parts were introduced after 1884, the general design and the circuits of the board were not materially altered for some years.

During these years the telephone exchange business had been very rapidly extending. Long-distance lines were being erected; overhead wires in some places were having such violent hands laid upon them that burial became necessary; the development of electric lighting and traction and the production of powerful currents disposed to extend unduly their sphere of influence—all these causes had their effect upon telephone switchboards. Metallic circuit service had to be provided for, and as the change must necessarily be gradual mixed service had to be given first. This requirement was met with a minimum of change in existing apparatus. The earth circuit multiple had in the test wire a line which could be made available as a metallic return by a slight change. The engaged test, as you will recollect, depended upon there being an earth connected to the test circuit. Put an earth on a metallic circuit line when engaged, leave it off when not engaged, and you have the necessary dual condition for negative or positive information. This earth was attached to one or both limbs of the cord circuit, and formed a part of the local circuit, which was completed by the plug in the act of testing. Between the earth and the cord is placed a retardation coil, which prevents currents of high frequency from either entering or leaving the telephone line, but is no bar to the simple battery current required for the test. This may be termed a transition board, but it is a very practicable one.

The importance of accurately balancing the talking lines, as well as the certainty of the test signal, showed the advisability of going back to the original 1879 plan of using a test circuit entirely distinct from the line circuit; and I think that this importance was insisted upon by none more strongly than English telephonists. But here a difficulty presented itself. Experience showed that as the jack contacts in a board increased, so did the troubles due to poor contacts between the line spring and its contact stud. Supposing a 4,000-line board of normal dimensions, on the single or mixed circuit system, there would be 21 jack contacts in the line. To adopt the system of cutting out the indicator with metallic returns, and to employ a separate test circuit as well, would require three contacts in each jack; so that a 2,000-line board of such a character would have 33 jack contacts, or about 50 per cent. more than a single or mixed circuit board of twice its number of subscribers.

With the general improvement in the quality of external lines, it is obvious that it would not do to put into the switchboards apparatus of such a design as would lead to defects in the very portion of the circuit under the electricians' immediate

Digitized by Google

control. This consideration led to another new departure—the last to which I shall call attention—and that is the arrangement of the subscribers' lines in an unbroken circuit throughout the board, with no contacts whatever in the jacks, and the automatic restoration of the indicator. The branching of the line contacts and the use of bridging indicators in themselves are no new departure in switchboards. The Post Office use branched line contacts and bridging indicators. It is of interest also to note that their indicators need no manual restoration, but the means by which these results are accomplished are not available for the methods of exchange working generally adopted. New means had to be invented. The idea had been "in the air" for a considerable time, but, as usual, lacked the final touches to make it practicable, like the invention of the telephone itself. I will indicate one of the principal difficulties. Let us suppose that two subscribers are connected, say No. 1 and No. 3,000, the connection being made at No. 1 board. The indicator of No. 3,000 is at the other end of the room. On sending a clearing-out signal, both indicators would drop unless cut out, as in the older system, or prevented in some new way. One of the earliest attempts at meeting this requirement was in Scribner's English patent No. 20,099, December 9, 1890, which was one of the preliminary steps in the branching system so far as the jack contacts were concerned. The desirability of the separate line for test purposes, however, helped the solution. This test circuit might very well bear an additional burden. The application of a locking device on each indicator, and controlled by a battery in the test circuit, was the first stage. The locking was a necessity, but it is only natural that it should have led to the restoration of the shutter to its normal position, thus rendering another of the switchboard operations automatic. The first design for the circuit of this board was by Mr. Bell, one of the switchboard experts of the Western Electric Company. But, in addition to the Western electric staff, the design of the board was so fully discussed by the switchboard committee appointed by various telephone companies, that I am unable to give, as I should like to do, the individual credit for details.

The indicator spring-jack and plug are illustrated in the diagram. The indicator consists of two coils mounted on opposite sides of a plate. The longer coil is the operating coil, and it is connected in bridge across the line. The short coil is the restoring part, and is connected in the test circuit. The operating coil when energised attracts the armature, to which is attached the arm holding up the shutter. The shutter opens out if the test circuit is incomplete. But if the test circuit is completed by having a plug in any jack of its line the restoring coil is energised and the shutter prevented from opening. The spring-jack has three springs, a bush, and a testing ring. The short spring is the contact from one limb of the line, the bush the contact for the other limb. The two springs of even length are the contacts for the test circuit. The plug has three contact surfaces. The point engages with the short springs, the sleeve makes contact with the bush of the jack, and the ring between the sleeve and the tip connects together the two test springs, thus closing the test circuit and restoring the indicator. The advantage of this construction is that there are no make-and-break contacts in the jacks whatever, and in this switchboard we reach the highest development so far in combining the most perfect talking circuit, a mechanism free from the liability of previously-existing troubles, and at the same time a reduction in the manual work.

Comparing 1880 with 1894, it will be observed that in an exchange to which I have already referred, having about 300 subscribers, it was considered necessary to provide a minimum of one operator to 25 subscribers. In the latest London switchboard to which I have referred, fitted for over 3,000 subscribers, there is a maximum provision of one operator for 50 subscribers, and in other places on boards of the same system 100 subscribers are attended to by one operator. The number of operators to subscribers is entirely dependent on the load line of the exchange, and there will be necessarily great differences, according to the nature and number of the calls. It will therefore be seen that the development in switchboards has followed the general law of enabling more work to be done with less labour.

The latest switchboards fitted in London are on the branching system, and it is needless to say that they contain many features originated by those who have the responsibility of their fitting up and maintenance. I hope the omission of detailed information on these points and many others will not be construed as an absence of recognition of the value of the work done outside the limited number of persons to whom I have referred.

I have advisedly limited this outline sketch to a record of what has been accomplished in the line of switchboards whose merits are to some extent guaranteed by general recognition, and I have also advisedly omitted any reference to complex problems, such as trunking systems between separate exchanges. I do not propose to anticipate the result of experiments now in progress, or presume to speculate on the possibilities of the future, but I would like to be permitted to make one comparison of the present with the past. The progress of telephony has been the subject of some comment. There are differences in that progress—of course local circumstances and conditions will mostly account for them—but let us make a comparison without going away from home. Between the setting up of the first and the last telephone switchboards to which I have drawn attention, there has been an interval of 15 years. We are accustomed to regard 1837 as the date of the introduction of the electric telegraph, although, of course, active work in a commercial way had not then commenced. Fifteen years after 1837 there was no public telegraphic communication between London and Brighton. The charge for a message of about 100 words to Liverpool was £5. These charges were regarded as high. "But no doubt," says a contemporary record, "these will be diminished when the company's arrangements get more matured, and they are better able to transact any amount of business which may be offered to them. The directors appear to be acting on the policy of checking, rather than encouraging, the use of the telegraph by the public until their establishments are everywhere in perfect working order." Now the most maligned telephone companies have never, I think, been accused of turning away customers. Notwithstanding the novelty of their business, they have been able to invite additions instead of requesting withdrawals. That undoubtedly was largely due to the extent to which the telegraph had prepared the way. Men experienced in the laying of lines and the management of instruments were already obtainable; but there is one direction in which there had been no previous experience of any moment, and that is in the methods and mechanism of intercommunication. The invention of the telephone was defined by judicial authorities as the creation of a new art. The greatest utility of that new art has been found in the development of that means of intercommunication, the exchange system, and the most important feature in the exchange is the switchboard. It has been a very easy task for me to pick out landmarks and put them together to show the route which was probably traversed; but members of this Institution are too familiar with such matters to need reminding that it was by no means so easy a task to devise and manufacture, or set up and maintain in working order, intricate apparatus, which should keep ahead of the ever-growing public demand for telephonic communication. I think, however, there can be no doubt that but for the invention and adoption of the multiple switchboard there would be some parallel between telephonic communication now and telegraphic communication at the date I have mentioned; its progress would have been checked by the impossibility of doing the work required.

Discussion.

The President, in proposing a vote of thanks to the author, said that the latter had come forward at a time when they had greatly needed communications on this subject.

The vote of thanks was then cordially passed.

Mr. Langdon, the well-known telegraph engineer, was indebted to the author for the interesting paper. He was very unacquainted with telephony, and the switchboards used on the railways were very simple.

Mr. Phillips, after paying a tribute to the author, remarked that the "Edison" board had been much improved from that referred to by the writer of the paper. He thought the amount of labour on the part of the operator was less in the case of the "Edison" board than in that of the Bell. The multiple board was a great feature, which had enabled numbers of subscribers to be dealt with. He then referred to a multiple board devised by Mr. Hoare and erected in Chancery-lane two years before that in Liverpool. The branch system, which was introduced in August last, had been a great success.

Mr. Hoare, who handed in photos of the historical board mentioned, explained the reasons for the design of the board, which had since that time been altered.

Mr. Calder having made a few remarks in reference to his experience in telephony,

Mr. Addenbrooke, who had endeavoured to design switchboards, stated that English telephonists were handicapped in comparison with their American brethren. As an instance he mentioned that an American company, in touch with all the telephone companies, had an invention department, where ideas and details were worked out to the general benefit. The author, he thought, had not sufficiently brought out the simplicity and perfection of the multiple board. The paper would form the basis of an enormous mass of interesting material, and he suggested that the testing departments, exchange systems, etc., should form the subjects of future papers.

Other speakers having addressed the meeting, the author replied and the proceedings terminated.

City Company's Engineer.—Mr. Frank Bailey has been appointed engineer to the City of London Electric Lighting Company, Limited, and Mr. J. Cecil Bull, the secretary, has taken over, as well, the duties of commercial manager. Mr. Frank Bailey will retain his position as engineer to the Metropolitan Electric Light Company.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

ANTI-SMOKE.

Schemes and projects for the suppression—partial or complete—of the smoke nuisance we shall perennially have with us, just as with the big gooseberry and "marriage a failure" topics, affording unlimited scope for everybody to speak freely, confidently, and (in many cases) ignorantly. Laws have been promulgated and passed for the purpose of putting an end to the pollution of the atmosphere by carbon compounds; innumerable sums of forty shillings and costs have been forfeited to the majesty of law; commissions have sat and inventors pondered, yet things are very much as before, though, unfortunately, we cannot say that "nobody seems one penny the worse." Finally, a complete range of trials and tests instituted by the Prussian authorities proves with tolerable clearness that all these efforts lead to extremely negative results, and will probably continue to do so.

True, the enquiry last mentioned—which has just been summarised in a report—appears to have dealt with what we may call "industrial" smoke, rather than smoke in general; but in manufacturing centres, at least, it is usually the case that the large chimney stacks are at fault. In residential towns, and notably in London itself, the mere numbers of domestic chimneys, each contributing a small quantity of absolutely foul smoke, effect quite as great an annoyance as ironwork stacks or chemical fume chimneys. The report of the Prussian enquiry states that in not a single instance of all the tests made with all the latest and most improved devices and methods, was it possible to obtain complete combustion without smoke—an exceedingly sage but trite conclusion, for it is what we all knew long ago.

One might discuss before an audience of engineers the questions of grate surface, chimney draught, fuel, design of boiler or furnace—whatever the purpose desired—but the actual and immediate end to be aimed at is not so much the greater consumption (or, which is the same thing, the less production) of foul smoke in a hundred thousand furnaces, as the reduction of the number of such furnaces. Suppose, for instance, that an average amount, s, of smoke is produced from n furnaces, then the total amount is $n\,s$. If we could effect a reduction of 25 per cent. in the number of furnaces, and also secure a saving of 5 per cent. in the smoke output by improved appliances (mechanical stokers, rocker bar grates, better calculated air admission, etc.), instead of $n\,s$ smoke, we should have a double economy leading to a result somewhere about ·71 of that amount, whereas the saving due to improved appliances alone (without reducing the actual number of furnaces) would merely give a result equal to about ·92.

It is, however, useless to enter into calculations of this type without going a little further and showing how such a saving is conceivably to be effected. In the first place, very much of the wanton waste and annoyance of smoke in the industrial districts must be ascribed to the fact that each individual works has its own source of power—its own engines, boilers, and chimneys. Obviously the great variation

Digitized by Google

in output required, and the splitting up of generating plants into small scattered units in this way, must lead to continuous bad working of the power source—bad, that is, in the sense of being uneconomical. It is so by reason, first, of the varying demand, and, second, of the smallness of the unit. If any serious effort is to be made in the direction of suppressing the smoke nuisance, it must lie in the concentration of power for industrial requirements. This does not mean by any means the concentration of works or of workers, but merely of the power-developing plants.

How else can this be accomplished better than by the employment of electric energy? Distance from source to point of application matters little for such a service, and hence a centralisation of power is at once not only feasible, but economical. There is at present, we regret to say, hardly a single large factory or works where at least two or more engines or like sources of power may not be found, the number practically increasing with the area occupied by the works, in order to save the waste and expense of countershafting or other connecting gear. These prime movers cannot possibly have the same careful and economical attention or operation as much larger units assembled together in one large central supply station designed for the special purpose with every conceivable improvement for preventing smoke and other waste.

The same can be said with reference to the second great source of air pollution—the domestic or house fire. We are all familiar with the excessive wastefulness of the open firegrate, sending out merely a small percentage of its heat energy into the room, yet so beloved of the English heart for its ruddy glow and cheerful aspect. There is, however, probably even a greater chance for improvement here than in the industrial furnace. The fair sex is proverbially—or naturally, let us say—inclined to comfort and cleanliness; and when the advantages of electric cooking and heating have been a little more widely diffused by their present champions (to whom every single person interested in electrical matters may well wish success), half the battle will be won—and let us hope, also, that half the house chimneys will find their occupations of taking fire or bringing down smoke gone for ever, and that this nuisance will be mitigated, if not entirely removed.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

EXPLOSIONS AND HOW TO PREVENT THEM.

SIR,—As I was the first in London to lay electric light cables underground for the use of business establishments, my experiences with explosions and the simple means adopted to stop them may be of service.

Our first explosion occurred in the year 1882, in the Brixton-road, near the Bon Marché, and as there were then no Board of Trade enquiries on electric lighting the matter dropped; but when we had a second, and shortly afterwards a third explosion, something definite had to be done to stop any further chance of accident. I was then convinced that the explosions arose principally from want of proper ventilation in the porcelain pipes through which the electric light wires were laid, and I adopted the simple plan of ordering the lids of each trap to be lifted for a few minutes every morning, but finding daily attention troublesome, we perforated a few of the covers with a drill, and after this was done the explosions ceased.

In all cases where electric light mains are laid in underground conduits the ventilation ought to be good, and means provided for accumulations of water to gravitate into the sewers. Where communications with the sewers are not allowed, "sump" holes or tanks ought to be sunk to receive the water, which could be pumped out at intervals. If these precautions were intelligently adopted London would in future be free from explosions, which are caused principally through imperfect ventilation. The sparking is no doubt produced by the heavy traffic of the streets causing the electric light wires, connected with screws in the boxes, to vibrate.—Yours, etc.,

A. L. FYFE.

Electric-avenue, S.W., January 22, 1895.

COUPLING FOR RAILWAY BRAKES.

SIR,—Could you tell me whether there is any reliable coupling for electric railway brakes. If so, in what number shall I find it? What has become of the Electric Traction Company? Have they been wound up or amalgamated?—Yours, etc.,

A. M. BUSHELL.

London, January 19, 1895.

REVIEWS.

The Indicator and its Practical Working. By A. G. BROWN. Manchester and London: The Globe Engineering Company, Limited.

This is a new edition of a well-known book dealing, of course, more particularly with the indicator and other steam-using appliances manufactured by the author's firm. We do not obviously attempt to criticise the qualities or standing of these devices, as compared with those of other makers, but can unhesitatingly speak of the book itself as being a most valuable work for all engineers and steam users. It not only contains a mass of useful tables and formulæ connected with steam-engine economy, but also may be characterised as a scientific treatise on the theory and proper employment of the indicator in general. The diagrams alone are worth study by all who have to deal with steam-engines, for they represent something more than scholastic tests on motors of antique form, being taken from the most modern types of engines in regular service. We again recommend the book to all interested in steam raising and use.

THE DESIGN AND EFFICIENCY OF PLANT FOR THE TRANSMISSION OF POWER BY ELECTRICITY.

BY W. C. MOUNTAIN.

(Concluded from page 68.)

Having considered the loss in cables and in transmitting power from a steam-engine of small size, but of a fairly efficient type, over a distance of 440 yards, it becomes necessary to consider, comparing this system with steam power, what the loss would be, assuming steam had been used. Referring to the losses due to the condensation of steam in long pipes, attention may be drawn to some tests carried out by Mr. Hy. Davey, M.I.C.E., on a 7½in. diameter steam-pipe, 1in. thick and 1,100ft. long, conveying steam at a pressure of 45lb. per square inch to an underground pumping engine in the Morton pit at Clay Cross, the pipes being covered with a non-conducting cement. As the result of careful observation, it was found that the condensation of steam in the pipe amounted to 500lb. per hour when the engine was standing, and 750lb. per hour when the engine was working, equivalent to ·183lb. and ·274lb. per square foot of surface of pipe per hour respectively.

In another experiment, carried out by Mr. W. Worby Beaumont, M.I.C.E., at the Staveley Hill Collieries, it was found that in a total length of 2,300ft., 1,900ft. of which

Digitized by Google

was underground, and covered in some instances to a depth of 2ft. with rough stuff, left after cutting away the coal, the condensation in a 6½in. pipe, 1½in. thick, conveying steam at an average pressure of 34lb. per square inch, was 600lb. per hour with the engine standing, and 1,400lb. per hour with the engine at work, equivalent respectively to a condensation of ·113lb. and ·265lb. per square foot of surface of pipe per hour.

In dealing with the losses under the second head—viz., those due to the inefficient working of the engine at low loads—it will probably be sufficient for the present purpose to briefly consider the conditions under which such engines work. In most instances the engine has been originally put down of an ample size for the maximum power likely to be required from it, while the average power is in the majority of cases probably 25 to 50 per cent. of the maximum power likely to be required from it, while the average power is in the majority of cases probably 25 to 50 per cent. of the maximum. Working under these conditions, especially with non-condensing engines, it is not surprising that the results obtained are very uneconomical. Perhaps the most striking instance of the wastefulness of this method of working is to be found in the following tests, carried out on some small workshop engines at Birmingham :

Nominal horse-power.	Probable i.h.p. at full load.	Average actual i.h.p. per hour during test.	Coal consumption in lbs. per i.h.p. per hour during test.
4	—	2·96	36
15	45	7·37	21·25
20	60	8·20	22·61
15	45	8·60	18·13
25	75	23·64	11·86
20	60	19 08	9·53
20	60	20·	8·50

These figures are interesting, as they actually represent the loss in steam-pipes which have been well covered, and upon engines of a size generally found in workshops.

In our president's very valuable address, which has, to a great extent, completely cut the ground from under the writer's feet, he has brought forward some most valuable information respecting the consumption of steam in engines in his own works, and on reference to his figures it will be seen that they correspond very nearly with the efficiency of the small engines which the writer gives above. The writer has further prepared an estimate of the approximate cost of (1) a complete steam-power plant, consisting of boilers, steam-pipes, and 10 horizontal engines each of 25 effective horse-power : (2) an electric plant, consisting of a high-class compound steam-engine, with boiler, dynamo, conducting cables, and 10 25-h.p. electric motors :

No. 1.—*Steam-Power Plant.*

Four boilers 30ft. long by 7ft. diameter, complete with fittings and mountings	£1,400
Foundations for four boilers	500
Ten horizontal steam-engines, each of 35 i.h.p., or, say, 25 effective horse-power, each £160	1,600
Main steam-pipes connecting the four boilers together, with branch steam-pipes for the 10 engines, at £60 each	600
Erecting four boilers, 10 engines, and 10 lengths of piping	500
Foundations for 10 engines, at £20 each	200
Total	£4,800

No. 2.—*Electric Plant.*

Two Lancashire boilers, each 30ft. long by 7ft. diameter, for a working pressure of 120lb. per square inch, complete with fittings and mountings	£700
One compound horizontal condensing steam-engine of 400 i.h.p.	950
Foundations for engine, boilers, dynamos, etc., exclusive of chimney	300
One dynamo, output, say, 225 units	1,000
Driving ropes	50
Main switchboard, with measuring instruments	100
Ten electric motors, each of 25 effective horse-power, at £140	1,400
Cables for 10 electric motors, say, £20 each	200
Foundations for 10 motors, say, £5 each	50
Erection of plant, say	250
Total	£5,000

From the above it will be seen that the first cost of the steam plant may be slightly less than the electrical plant, but it will be necessary now to turn to the cost of working, and two approximate estimates are given—No. 1, of the approximate cost per annum of 3,000 hours for maintaining the steam plant; No. 2, the approximate cost per annum for maintaining the electrical plant. This calculation is based on the assumption that the 10 small engines will each consume 40lb. of steam per indicated horse-power per hour, or, say, 56lb. per effective horse-power, and to this an allowance of 20 per cent. has to be added for condensation in steam-pipes, making the total consumption of steam equal to 68lb. The evaporative efficiency of the boiler is taken at 6lb. of water per 1lb. of coal, which the writer considers a very ample allowance for the class of coal which is used in most engine works. Therefore the consumption of coal per effective horse-power will be, say, 11lb. per hour. In the electrical plant, the coal consumption is based on the assumption that the engines will require 15lb. of steam per indicated horse-power per hour, and the indicated horse-power of the engine is taken at 400. The evaporative efficiency of the boiler is taken at 6lb. of water per pound of coal, which will be, say, 2½lb. of coal per indicated horse-power per hour.

Steam Plant.

Coal consumption for 10 engines, each giving 25 effective horse-power, or, say, 350 i.h.p.—*i.e.*, collectively 350 h p.—at 68lb. of steam per effective horse-power, including condensation in steam-pipes at 11lb. of coal per effective horse-power per 3,000 hours, working per annum = 3,683 tons, at 6s. per ton	£1,104	14	0
Labour—three stokers and four men to look after the four engines—total, seven men at 30s. per week, £10. 10s. per week for 52 weeks	546	0	0
Water for boilers—7,140,000 gallons, at 6d. per 1,000 gallons	178	10	0
Oil for 10 engines, at 7s. 6d. per week	195	0	0
5 per cent. interest on capital outlay, £4,800	240	0	0
5 per cent. depreciation on capital outlay, £4,800	240	0	0
The total cost, therefore, comes to	£2,504	14	0

Electrical Plant.

Coal consumption for 400 i.h.p at 15lb. of steam per indicated horse-power per hour for 3,000 hours at 2½lb. of coal per indicated horse-power per hour = 1,334 tons at 6s. per ton	£400	4	0
Labour—one stoker, one engineman, and one man to attend to electric motors, at 30s. per week ; £4. 10s. per week for 52 weeks	234	0	0
Water for 1,800,000 gallons, at 6d. per 1,000 gallons	45	0	0
Oil for engine and 10 motors, at 30s. per week	78	0	0
5 per cent. interest on capital outlay, £5,000	250	0	0
5 per cent. depreciation on capital outlay, £5,000	250	0	0
The total cost is therefore	£1,257	0	0

From the above it will be noted that the actual saving in favour of the electrical plant will be £1,247. 4s. per annum, so that the total cost of the plant would be saved in, say, four years compared with a steam plant, which would cost practically as much money to erect. The above figures show that an effective horse-power by a steam plant can be obtained for £10 per annum. An effective horse-power by electricity can be obtained for £5 per annum. The writer trusts that the above estimates, which are, of course, more or less approximate, will be criticised by the members present.

A practical example of the efficiency and saving of an electrical plant over a steam plant is obtained from the writer's own experience in his firm's works in Newcastle. Prior to the adoption of electric motors the works were driven by a Cornish boiler 25ft. long by 6ft. diameter, 60lb. working pressure, a semi-portable engine of 50 effective horse-power, and a vertical boiler of 20 h.p. The Cornish and vertical boilers steamed the engine in the machine shop, and also supplied steam to the engine in the erecting-shop for testing dynamos, the semi-portable engine being used for driving the erecting shop and pattern shop. As this plant occupied very valuable space, the writer's works being in Newcastle, where rents are very high, it was decided to take out this plant, and to put down a plant consisting of two locomotive boilers of 160 h.p. collectively, 160lb. working pressure ; one vertical compound steam-engine, with cylinders 9 by 18 by 10, giving approximately 100 i.h.p.; one dynamo to give an output of about 40,000 watts. This plant now drives electric motors in the pattern shop, erecting shop, foundry, and a number of small motors in the tool shop, etc., with the result that by the removal of the old steam plant from

Digitized by Google

the centre of the works a new shop has been erected, 90ft. long by 45ft. wide, two men have been dispensed with for attending to the engines and boilers, and the coal consumption has been reduced from 25 tons per week to about 12 tons per week, and it cannot be estimated that the annual saving is less than £700.

Class of Motor.

In laying down an electric transmission plant it is necessary to consider the class of motor most suited for the

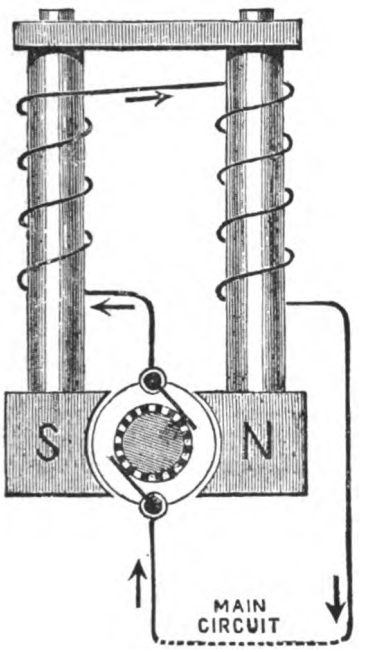

Diagram No. 4.

particular work that it is required to drive. Diagram No. 4 represents the winding of the magnets of a series-wound motor. Diagram No. 5 represents the windings of a shunt-wound motor. Diagram No. 6 represents the windings of a compound motor.

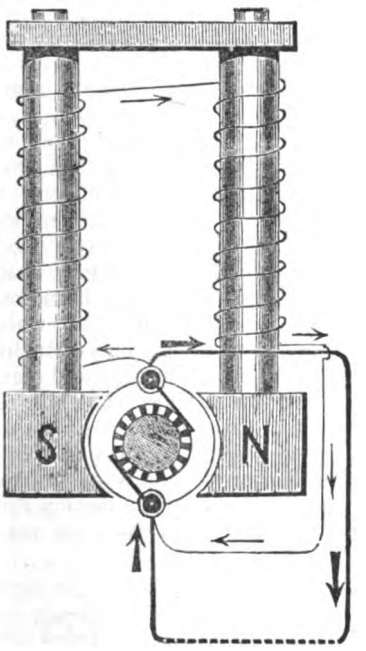

Diagram No. 5.

The series wound motor is used in positions where great starting power is required, such as for cranes, haulage gears in collieries, and for single motors for driving pumps and heavy machinery where the load is constant after being once applied. This motor, however, does not give a constant speed, and is therefore unsuited for machinery where the load is variable and the speed required to be constant. A shunt-wound motor has not the same starting power, or the advantage of running at a practically constant speed under any conditions of load, and is therefore particularly suitable for driving light machinery where it is necessary to maintain an absolutely constant speed under varying loads.

A compound-wound motor (which is a machine very seldom made) is a combination of a series and a shunt machine, and whilst it has not the perfect regulation of speed that can be obtained from a shunt motor, it has the advantage that by the addition of a series coil considerable starting power can be obtained. This type of motor the writer has fitted on to cranes, where the motor is allowed to run constantly with great success.

Reduction Gear.

As a motor generally runs at a speed considerably in excess of the speed of the machine which it is intended to drive, it is necessary to reduce the speed by one or other of the following methods: (1) Worm gear.—The writer has supplied worm gear to electrical power plants with very great success, but if this gear has to run properly it must be very accurately made, and it is desirable that the worm should be at least double threaded, if possible treble threaded. A satisfactory material for the worm and worm wheel is case-hardened wrought iron for the worm, and phosphor-bronze for the worm wheel. (2) A very ingenious,

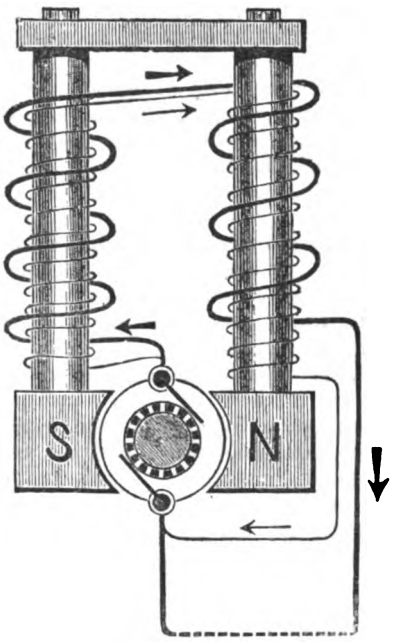

Diagram No. 6.

and at the same time compact and economical, type of reduction gear is the Humpage and Jacques, as shown. This gear, it will be noted, consists of bevel wheels placed in a box. The box can be filled with oil or other lubricating material, and the whole gear occupies very little space.

A third method is a reduction entirely by spur gearing. This method of driving is usually very objectionable, because it is almost impossible to prevent considerable jar upon the wheels owing to their high speed, with the result that it is not an unusual thing to see the wheels strip, and a vibration is set up in the armature of the motor which is almost certain to cause damage sooner or later.

A fourth system is a combination of belt driving and spur driving, the belt being placed between the motor and the countershaft of the machine. The belt acts as an elastic medium between the motor and the gear, it takes all vibration off the motor, and works extremely satisfactory.

A fifth system is entirely by belts, and probably for general work, particularly in engine works, this type of gear will find most favour.

It is, however, absolutely necessary to consider in laying down any works where motors are to be used, particularly for individual machines, that a more or less considerable loss exists in the reduction gear necessary between the motor and the machine, and it is not safe as a general

Digitized by Google

practice to allow less than, say, 15 to 25 per cent. for this loss.

The writer trusts that the remarks he has made, together with the comparative estimates and general information in the paper, will be of value to the members, and regrets having taken so much time.

A NEW MINING MOTOR.*

BY HENRY A. MAVOR.

The ever-increasing size and depth of mines, as minerals are worked out of the more easily accessible fields, call for the application of power at ever-increasing distances from the points where power can be conveniently generated. The use of mechanical power for the operations of ventilation, hauling, pumping, and coal cutting is gradually increasing, while the conditions of work in the mines are becoming such as to render the use of the older methods of power transmission increasingly difficult. Transmissions of power by steam, air, water, or ropes, all present increasing difficulty as the distances are increased, so that the attention of mining engineers is now strongly directed towards the possibilities of power transmission by electricity.

The wise conservatism which prefers to proceed upon the lines of the old and painfully acquired experience is from time to time broadening its base and including in its grasp another weapon with which to grapple with new or increased difficulty.

The beautiful simplicity of electrical apparatus goes far to compensate for the disadvantages introduced by the application to the mine of another style of plant to which the miners have to become accustomed, and the great efficiency under suitable circumstances of electric plant more than compensates for the losses incidental to the transformation of energy from one form to another. It is not be supposed, however, that the electrical engineer pleads for his methods of power transmission a universal advantage over all the established methods. In most cases it will be found that for simple transmission, up to about half a mile from the source of power, the older methods will be less costly and as efficient for moderate powers. The losses due to transformation of mechanical to electrical energy, and the retransformation to mechanical energy, bear too large a proportion in such cases to the loss in transmission to admit of a favourable comparison with any method where the energy is directly transmitted without transformation. For longer distances electricity shows a rapidly increasing advantage in first cost and in efficiency, and also in the important element of convenience. Electric cables and electric motors are the most compact and portable means for conveying and using power underground, and in such operations as coal cutting and dock pumping, the ease with which the power may be made to follow the work is of enormous advantage.

These general questions have, however, been pretty fully gone into in Mr. Scott's paper, read before the institution in 1891, and in the discussion on that paper, and need not more be enlarged upon.

The conditions of coal mining specially require that any machinery used in the mine must conform to certain conditions, all of which may be met by an electric motor constructed specially for mining purposes. The first essential is certainty of working. The motor must not break down; it must be light and easily handled; it or its parts must be of such a size that they can be conveniently passed down the shaft and along the roads; it must be efficient; and, lastly, it must be as cheap as possible, consistently with these other requirements. Power plant underground is usually vitally connected with the working of the mine. If the pump, fan, or hauling rope stops, the least possible result is serious and prolonged inconvenience. Now, the state of matters in a coal mine is not such as is most conducive to the welfare of electrical apparatus. The temperature is high, dust and damp are in the air, and the engineers are accustomed with ponderous slow-running plant requiring little attention. The motor must therefore not only be well constructed mechanically and electrically, but it must be suited for working under conditions to which in ordinary circumstances electric plant is not subjected.

Considerations of economy and efficiency tend to the use of as high an electric pressure as possible, but for the generality of coal-mining work in this district, an E.M.F. of 500 volts is found to be sufficiently high. The insulation of armatures for this pressure is comparatively simple, but great care has to be taken in all dynamo machines that they are of sound mechanical structure. This presents some considerable difficulty, because the electrical and magnetic requirements are not on the whole consistent with the mechanical conditions.

As is well known to most hearers of this paper, the action of the electrical motor depends on the force exerted between what is called a magnetic field and conductors carrying an electrical current. To attempt to explain this action to engineers who have not given any study to the question generally leads to failure and mutual recrimination. Undeterred by the experience of others, I make another attempt, in the hope that it may be possible to convey some idea of the mode of action as it presents itself to the mind of the electrical engineer.

Although it has to be admitted that the whole matter is still in the region of speculation and hypothesis, it must also be borne in mind that many of the operations in nature are involved in much deeper mystery. The bases of the phenomena of life are hidden in still impenetrable obscurity, and the cause of such a familiar phenomenon as that of gravitation is so far from being understood that Lord Kelvin wrote of it only last year: "Absolutely nothing has been done either by experiment or observation towards deciding between Newton and Bernouilli as to the question of its propagation through a medium, and up to the present time we have no light even so much as to point a way for investigation in that direction."

Strangely enough, the much more recently observed phenomena of electromagnetism have led to the development of theories which have all the appearance of consistency with the observed phenomena. Without entering into any elaborated quotation of authorities, I will give you what appears to be the most approved way of looking at the phenomena with which we are concerned in studying electric motors. For our present purpose we need concern ourselves only with such electric currents and such magnetism as we have to do with in continuous-current motors—that is to say, motors driven by a current of approximately steady flow in one direction. As current and magnetism are but two aspect of the same phenomenon, it matters little from which end we attempt to unravel their connection. Beginning, then, with the electric current, we must picture to ourselves that wherever an electric current is started in a conductor there is set up all round it in the medium—which has been postulated for the convenience of natural philosophers, and which they call the ether—a whirling disturbance. This disturbance is at right angles to the direction of the current, and seems to answer to the description of a vortex ring. The ring rotates with the current as its axis. It is supposed that this ring is made up of whirling electricity, so that it has, like the more visible and familiar vortex rings of smoke, two motions without change of position. The motion round the axis of the rings produces the phenomena of magnetism. We

Fig. 1.

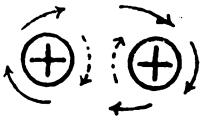

Fig. 2.

may then represent a section of our electric circuit as being surrounded by a whirl in a definite direction. It so happens that the direction of this whirl, in relation to the direction of the current, is represented in driving a right-handed screw home. Thus a current into the plane of the paper would have a whirl as shown by the arrow (Fig. 1). Now place alongside of it another conductor similarly carrying

* Paper read on December 18, 1894, before the Institution of Engineers and Shipbuilders in Scotland, and printed in the *Transactions* of the institution.

Digitized by Google

current, and we have a whirl enclosing the two conductors, the stream of lines continuing in the direction of least resistance, as shown in Fig. 2.

The strength of this whirl, or whirls, which is what is called the magnetic field of the current, depends on the nature of the substance or substances through which it passes. In a path consisting entirely of air, its strength is very small. In a path consisting of iron or steel, its strength or intensity is very much greater. A group of such whirls might be represented thus (Fig. 3).

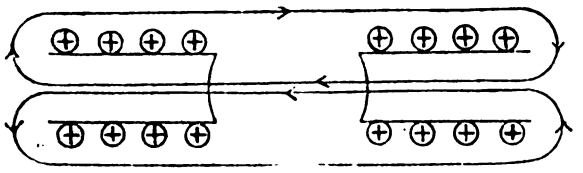

FIG. 3.

If, now, a conductor with whirls of its own be introduced into this group of whirls, or magnetic field, we are in a position to guess how it will behave (Fig. 4).

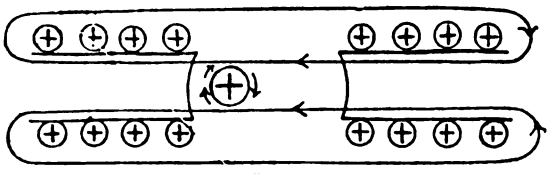

FIG. 4.

It will be seen that the whirl in the intruding conductor opposes the stream of lines on one side and adds to them on the other; the tendency, therefore, will be to move towards the direction in which it is pushed by the most lines. That is upwards in the case shown in the sketch. This is, in fact, the action of the electric motor. Electric currents are sent in from an outside source and made to flow in the directions indicated, and the result is motion in the direction shown. The aim, then, in designing an electric motor is to provide as nearly as possible a continuous iron path for the magnetic whirls set up by the exciting current, and so arrange the conductors carrying the currents to be moved across the magnetic field at right angles, that they shall interrupt this iron path as little as possible, and that they shall transmit the driving force to a point where it can be applied to do work. This is now practically accomplished almost universally by essentially similar methods. A portion of the iron path is mounted on an axis, and is free to revolve. On this portion are mounted the driving conductors, which transmit to the axis the force exerted by the interacting currents and magnetic field by exerting a turning force at the periphery.

To get this force applied as it is wanted, it is necessary to confine the electric current to the copper conductors, and to so mount those conductors on the core that they will transmit the forces to the shaft.

(To be continued.)

ARC LIGHT CARBONS.*

BY B. F. MILES.

Arc light carbons are to the electric arc lamp as the wick is to the oil lamp, or the burner to the gas-jet. The best arc lamp cannot send out its piercing light without a good carbon, while the best carbon in a poor lamp can only emit a feeble glow. One often has to bear the odium due to the faults of the other, but in both perfect combinations are necessary before the dark places of the earth can be made bright as noonday.

To the casual observer an arc light carbon is a very uninteresting object. It is usually a cylinder varying from $\frac{3}{16}$in. to 1in. in diameter, and from 6in. to 14in. in length. Its colour is a deep bluish-grey or black. Oftentimes they are coated very thinly with copper, nickel, or zinc, which completely changes their appearance. In most cities in this country the copper-coated variety is the one usually noticed in street arc lights, while in Europe the black, uncoated variety is almost wholly burned.

* *The Electrical World.*

These unpretentious little cylinders, however, have a long history, and the process by which they are made is an extremely interesting one. About 1810 Sir Humphrey Davy, in his researches in electricity, discovered that small cubical sticks of carbon whose points were separated from each other about the sixteenth of an inch, would emit a brilliant flash of light when a current of electricity was passed through them. These carbons were composed of powdered wood charcoal mixed with a little syrup of tar moulded into shape under a pressure of about a hundred pounds to the square inch, and baked in a crucible in a very hot fire. During the next 70 years numberless experiments were made in Europe and in this country to produce carbons from a variety of mixtures. The electric dynamo and arc lamp, not having been perfected until the closing years of the decade, 1870-80, the demand for carbon electrodes was very limited, their principal use being in scientific research; consequently they were only made by hand in two or three continental laboratories on the smallest scale, and at a very high cost. In 1876, the principal French maker sold his product at 35 to 40 cents each, a price that was practically prohibitive.

With the birth of the wonderful Brush dynamo and arc lamp a large commercial demand was quickly created, and how to supply carbons of high quality and at a low cost became a problem for electricians, second only in importance to the invention of the arc lamp.

The first step in this problem was to find suitable raw materials. Search had been made on both continents with comparative failure. Of the many sources of supply suggested, carbon produced in gas-retorts seemed the most feasible, but the varying impurities and refractory nature of this material had made it at best a makeshift. Till the fall of 1878, however, it was the principal source of supply, and carbons were still made in rectangular cubicular form with blunt ends.

The first American carbon manufacturer and his factory deserve mention here. This was David Thompson, of Newark, N.J., who died recently at a good old age. The writer remembers well calling on him nearly six years ago, and walking from his unpretentious little wooden house through his grape arbour to his small two-storey workshop. It was only about 20ft. broad by 30ft. long. A hand mortar, a rude brick oven and mixing pan, a hand bolting and grinding outfit, with a few iron and steel moulds, comprised his entire "plant." He still kept the small rectangular blunt iron moulds with which he made the first arc light carbons produced in this country, and spoke sadly of the business as having far outgrown his little means.

The present high position of the American carbon industry is due to two men, the celebrated inventor Charles F. Brush and Washington H. Lawrence, one of the founders with Mr. Brush, of the Brush Electric Company, and now president of the National Carbon Company, Cleveland, Ohio. While engaged in the invention of his arc dynamo, Mr. Brush had been investigating the nature of carbons and planning for their manufacture. In 1877, with Mr. Lawrence, he began a series of experiments on petroleum coke. After others had searched over two continents, it seems almost ridiculous that Mr. Brush found the desired supply of commercial carbon in its raw state within a mile of the Brush Electric Company's works; yet such is the fact. The Standard Oil Company for years had been burning up the last product of the distillation of crude oil, formed at the bottom of its paraffin stills. Shovelled from the stills in great lumps like the largest anthracite coal, it also resembles the latter at a little distance in its shiny, black appearance. It was this refuse product that was to help in giving the world its most brilliant light.

At first, Mr. Brush was puzzled over some properties of the new material. While it is pure carbon, it is also, like the purest anthracite coal, a non-conductor of electricity when in a raw state. After having heated the coke in a little crucible held in a forge fire, he found the non-conductor changed into a conductor, and the main result was gained. The balance of the experiments were conducted principally to ascertain the grain best adapted for burning in the electric current.

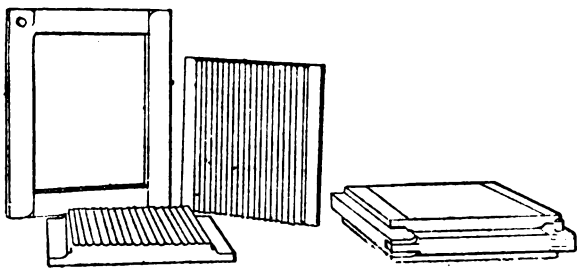
These results attained, it was decided that the best adhesive material to bind the particles of carbon together

Digitized by Google

was coal tar pitch. This is the practice to-day, varied by such other slight additions as the experience of manufacturers have found to be advisable. These admixtures are kept as trade secrets, and as the carbon after moulding is baked at a very high temperature, it is very difficult to discover exactly what has been used.

The first large carbon works built still exist. It is the plant connected with the factory of the Brush Electric Company at Cleveland. From this plant many other factories have started. The writer believes all in this country have adhered closely to the materials which Mr. Brush determined as best for the business, and have followed closely the processes designed by himself and Mr. Lawrence.

These processes of manufacture may be summarised as follows: The petroleum coke is crushed and carried into retorts heated to a high temperature, where it remains from 10 to 50 hours, according to the result desired to be produced, thereby the moisture is driven out and the quality of conductivity imparted. Next, the carbon is carried to mills in which it is ground to a fine flour, next bolted and carried to a pan in which it is to be mixed with the "binding" material. All this seems very simple, but when one remembers that petroleum coke and diamonds are carbon, and that fine petroleum coke is nearly as hard as diamond dust, it is seen that the process requires exact machinery of great power, and that much care must be exercised in each of the subdivisions of the process. When in this stage, the carbon has the physical characteristics of the ordinary wheat flour of commerce, save that it is black.



MOULD FOR 7-16 INCH CARBONS.

In combining the carbon flour with the pitch, the latter is first broken up in an ordinary crusher, then transferred to mixing kettles or pans. The proportions of carbon flour, pitch, and its associate mixtures vary according to the "softness" or "hardness" of the carbon desired. These mixing kettles and pans are kept warm, and the entire mixture is constantly agitated by hoes, or other devices, from 15 minutes to an hour. This heat causes the particles of pitch to attach themselves to particles of the carbon flour, and at the completion of the process the mixture has the appearance of black pebbles of various sizes mixed with coarse black sand. After this mixture has cooled it is again crushed, ground, and bolted so that a flour of uniform grain is produced. The machinery employed for this purpose is somewhat different from that used in wheat flour mills, but the modifications would not interest an untechnical reader.

Thus far the process has not been of much interest to the ordinary observer. From now on the work becomes quite interesting. The material takes one of two courses, according as it is to be made up into "moulded" or "forced" carbons. If the first, the material is brought to men working at benches, who are called moulders. They are provided with steel moulds split in half, grooved according to the length and diameter of the carbon cylinders to be made. The steel of which these moulds is composed is of the finest quality, else it will not retain its shape under the tremendous pressure employed.

The moulder weighs the flour in a scale, distributes it evenly over the entire surface of the mould and upon it places the proper steel cap. The mould is then very slowly heated, which causes the particles of combined pitch and carbon flour to to take a form resembling thick paste. When the proper degree of heat has been obtained, the mould is taken from the furnace and placed under a hydraulic press, the pressures employed varying between 100 and 400 tons. From the presses the moulds are taken back to the bench, the cover and sides removed, and the card of carbons very carefully lifted off. When these cards of carbons become cool, each carbon is separated, and the little fin that has held it to its neighbour is scraped off each side, so that the carbon is left a perfect cylinder.

As mentioned above, the first carbons made were rectangular in cross-section with blunt ends. The modern practice is to make them cylindrical, with points more or less like the ends of a sharpened pencil. This change was suggested by Mr. Brush from his observations upon the shape which carbons acquired when burning in an arc lamp. He noticed that carbons whose cross-section is a circle cast much less shadow upon the surfaces to be illuminated than those whose cross-section is a square; also that all carbons burning in the electric arc tend to shape themselves like pencils, and do not form a quiet arc until they have assumed that outline.

The former observation could not be made the basis of a patent. The latter combines points of utility, both in cost of manufacture and in the initial half-hour of burning, and is the subject-matter of one of the Brush, also one of the Lawrence, patents which are still in force.

The majority of the carbons consumed in this country, being burned in lamps fed by a constant current, are made by the moulded process, to which they seem best adapted. In Europe, on the other hand, the majority of arc lamps are on constant-potential or alternating currents, and require a carbon whose particles are arranged differently from those in the moulded process, and also in many instances a core of less dense material to ensure steadiness of light.

The flour for carbons to be made by this process is treated somewhat differently than that of the moulded variety. It is usually shaped into cylindrical "plugs," about 6in. in length and from 2in. to 6in. in diameter. These are placed in front of the plunger of an hydraulic press of horizontal action and are forced through its jaws, taking any desired cross-section from the outline of the die at the mouth. As fast as the carbons leave the die they are received upon a table and cut to desired lengths. Should the carbons be "cored," a "core" or hollow about an eighth of an inch in diameter is left in the centre of the carbon as it passes through the die, by the action of a "tongue." This all can be readily understood by imagining the action of the human tongue and breath when ejecting a stream of water. The water corresponds to the carbon "plug"; the lips to the die at the mouth of the press; the breath to the press plunger forcing out the carbon; and the tongue tends to produce a hollow or core in the liquid stream.

(To be continued.)

HULL ELECTRIC LIGHTING EXTENSION.

A report has reached us from Dr. Holder, chairman of the Electric Lighting Committee of the Hull Corporation, in regard to a visit paid last week by the Hull and District Institute of Engineers and Naval Architects to the Hull Corporation electric lighting station and the setting in operation of a new engine and dynamo and motor generator. The ceremony of starting the new engine was performed by the Mayor (Alderman C. Richardson), and that of the motor generator by the Sheriff (Mr. P. T. Crook). Dr. Holder conceived the idea of making the visit and the starting of the new engine one event, and, in response to his invitation, a large body of gentlemen attended at the station in Dagger-lane. The ceremony that evening marks another step in the progress of the Corporation electric light supply, which in the short space of time it has been opened has achieved remarkable success. The station was opened on January 16, 1893, to supply the old town of Hull. In response to a general request in the latter part of the same year, the supply was extended west of the docks. The larger demand necessitated last year an enlargement of engine and dynamo power, and a condensing plant, and now the installation of a new engine and dynamo and motor generator. The cost of the equipment of the station and service, which in 1893 had cost £23,072, has been nearly doubled, since the subsequent additions have brought its present cost up to nearly £40,000. Comparing the end of the year 1893 with the end of 1894, we find that the engine power has been increased from 560 to 860, and the capacity of the dynamos from 2,600 amperes to 4,200 amperes. The rapid growth of the demand and the general popularity of the light with the public may, in some measure, be gauged by the fact that the lamps connected in-

Digitized by Google

creased in the year from 8,035 to 14,208 of 8 c.p., and the units delivered to customers 74,600 to 163,357, the users increasing from 148 to 271. Thus, while the capacity of the station has been increased by a little more than half, the output has more than doubled. In the time under review efforts have been made to popularise the light by reducing the price from 7d. per unit to 6½d. for lighting, and 5½d. for places of worship, and from 6d. to 5d. for motive power.

Amongst those who were present were the Mayor (Alderman Richardson), the Sheriff (Councillor Crook), Mr. F. H. Pearson (president of the Engineers' Institute), Aldermen Wilde and Fraser, Councillors Skinner, McGaw, Shaw, Wharram, Wise, Ross, Marshall, Moulds, Broadberry, Newham, Laverack, Calvard, Brown, Butterworth, Briggs, Millington, Bell, Parrott, Cohen, Feldman, Simpson, Messrs. R. G. Reeks (Admiralty surveyor), M. Samuelson, J. R. Smith, J. Spear, W. Harris, E. Williamson, F. C. Brentano, Dr. Riley, T. Rose, C. Clark, G. Clark, J. H. Charlton, J. Mills, J. Innes, R. W. Carson, W. Cooper, H. McInnes, G. H. Strong, W. H. Willatt, Beath, R. Good, R. Hill Dawe (town clerk), W. H. Milner (borough treasurer), W. Linney, J. G. Hall, and W. Wheatley.

Dr. HOLDER, in the course of a short introductory address, said that Wednesday was their birthday. January 16, 1893, was the first time that they delivered a unit of electricity, and they were thus two years old. Unlike all other committees of the Corporation, they made up their accounts on December 31, and, therefore, their second year had just been completed. In their first year they delivered 74,000 units of electricity, and during the second year they had increased that by more than 100 per cent., their delivery being 163,000 units. Their income for the first year was about £2,200; last year, at a lessened charge, it was £4,800. In their first year they paid their way in an extraordinary degree, and Hull held the record of England for economical working. They paid every penny for upkeep, maintenance, taxes, interest, and everything, and had the nice little sum of £130 profit. The second year had been better. The accounts were not fully made out, but he had gone through the matter carefully in his own mind, and with the assistance of the borough treasurer, and it enabled him to say they had done exceedingly better, and would hold the record for economical working against any station which had been in existence for that time. They would not only be able to pay upkeep, interest, etc., but a twenty-fifth part of their capital, and have a few hundreds of pounds profit. He had been asked to give the reasons of the success of the station. The first was the wisdom of the Council in allowing two or three practical members—a builder or two, an artisan who was well acquainted with brick and timber work, and their friend Mr. Laverack—to visit different stations in England. When they went away they were helped by one of the members of the institute who was paying them a visit that night (Mr. Willatt), who lectured them all the way up and down, so that they knew, whatever station they were going to, what were its merits, where they were to look for what was wrong, and what they were to ask for. Through that committee the Corporation were made acquainted with the best plant, and that had conduced much to its success. The second point was that they knew what kind of an engineer they wanted, and how far they ought to trust him; and that they had had in Mr. Herman Lewis and his successor (Mr. Gibbings) two of the best electrical engineers in the country. The third element of their success was that they knew what class of plant they wanted, and who were the best manufacturers. They did not go to cheap people, but to good people, and that, he believed, was really the foundation of their economy in working.

The MAYOR extended a hearty welcome to the visitors. Mr. Holder had referred to the reasons why the station had been a success, but he (the Mayor) thought it was generally admitted, both in the Corporation and the town generally, that one reason why it had been so successful was that Mr. Holder had been the chairman of the committee, and had thrown into the work that enthusiasm which was essential to its success. Many present would perhaps remember the first introduction of electric light to Hull, and how unsatisfactory it proved, and how expensive it was to the ratepayers. The reason why that attempt was unsuccessful was, he thought, because it was not carefully considered at the commencement, and because the plant which was put down was of an unsuitable character.

Mr. PEARSON returned thanks for the kindly welcome they had received, and said that, when it was suggested several of the members would like to look round the station, they never expected they would be asked to a function like that. Some gentlemen would sit at the head of the committee, and do the routine work, but not the detail work, but he believed Mr. Holder had gone into the matter fully, and was as well acquainted with the subject as any non-professional man could be.

Mr. GIBBINGS, the electrical engineer, explained the working of the station.

The company, who had assembled in the battery-room, then adjourned to the engine-room, where Mr. Skinner, the deputy-chairman of the committee, asked the Mayor to start the new 300-h.p. engine and dynamo.

His Worship turned on the steam, and the large engine started working. The Sheriff next started the new motor generator. After an inspection of the machines and apparatus contained within the station, refreshments were served in the drawing office.

Mr. PEARSON moved a vote of thanks to Mr. Holder, which Mr. SAMUELSON seconded.

Dr. HOLDER replied, and the health of Mr. Gibbings, the electrical engineer, was also honoured.

RESISTANCE WIRE.

The Westphalian Rolling Mills (Messrs. Fleitmann, Witte, and Co.) of Schwerte, have appointed Mr. Al. Demaret, of 4, St. Mary-axe, as their representative in this country. The latter has forwarded us the following translation of a certificate of test which the Westphalian Rolling Mills received from the Imperial Institute at Charlottenburg:

Certificate of Test of Sixteen Kinds of Wire.

The Westphalian Rolling Mills (Fleitmann, Witte, and Co.) delivered on February 1 of the present year to the Imperial Institute 16 coils of wire, 0·02in. diameter, distinguished by numbers, together with a list containing the designations stated below, and the degree of hardness, for the purpose of being tested for specific resistance The test was made in the following manner: A piece of the wire was soldered at both ends to copper blocks, and then, after its length and cross-sectional area had been determined, the wire was wound on a strip of mica, and heated in a drying-chamber for 24 hours at a temperature of 130deg. Celsius (266deg. Fahrenheit). The resistance of this piece of wire was then measured in a petroleum bath at two different temperatures according to the Wheatstone method.

From the values thus obtained the following figures of the specific resistance and the variation of the same with the temperature were calculated:

Designation.	No.	Condition.	Resistance in microhms of a length of 1cm. (0·39in.) and a cross-sectional area of 1 sq. cm. (0·016 sq. in.) at 20deg. Celsius (68deg F	Variation of resistance by increase of 1deg Celsius (1·8°F.
Patent resistance wire Ia. Ia.	2	Hard.	50·2	−0·000011
Patent resistance wire Ia. Ia	12	Soft.	47·1	+0·000005
Patent nickeline wire I	3	Hard.	43 6	+0 000076
,, ,,	13	Soft.	40 7	+0 000077
Patent nickeline wire II	4	Hard	33 9	+0·000168
,, ,,	14	Soft.	32 3	+0 000181
German-silver wire.....	7	Hard	38·8	+0 000187
,, ,,	17	Soft.	39·3	+0·000195

A new quality, called "superior," was also sent for testing. The results were as follows:

Specific resistance in microhms of a length of 1cm. (0·39in.) and a cross-sectional area of 1 sq. cm. (0·016 sq. in.).	Coefficient of temperature.

PROPOSED RESUSCITATION OF WOODHOUSE AND RAWSON UNITED.

The Industrial Inventions Development Company.

We have received two circulars in regard to the Industrial Inventions Development Company, Limited, the object of which appears to be to resuscitate some of the business of Woodhouse and Rawson United, Limited. The first circular, which emanates from Mr. F. L. Rawson, is addressed to the shareholders and creditors of the United Company, and is as follows:

Since Woodhouse and Rawson United went into liquidation, nearly the whole of my time has been devoted to endeavouring to save the most valuable assets for the shareholders and creditors. It was inevitable that in the hands of a receiver the time which was absolutely necessary for the favourable realisation of assets could not be given, and that the bulk of the company's property would have to be sacrificed for almost any price that purchasers might choose to offer. But in the patents invented and perfected by my brother, Mr. W. Stepney Rawson, who was for many years our head technical expert, I came to the conclusion that there existed a source of large future profits, and that by their means the shareholders and creditors might in time recover a considerable part of their losses. This view has been borne out by subsequent experience. In addition to the metal pickling patents, Mr. W.

Digitized by Google

Stepney Rawson has, since the liquidation of the company, patented, with Mr. Richard Heathfield, a system of galvanising by electricity. Mr. Heathfield is a practical galvaniser with some 30 years' experience, holding an admitted position in the trade. Being satisfied that electric deposition must largely supersede the present system of galvanising by dipping in molten metal, and be a most valuable invention, I some time ago obtained the option referred to in the accompanying circular with a view to offering the benefit of such option to the shareholders and creditors of Woodhouse and Rawson United. Upon the necessary plant being erected at the works of the best known firm in the trade in England, the anticipations of the inventors were fully realised. The date by which the option had to be exercised was 14 days after the process was successfully at work, and as by that time I had not been able to complete my arrangements for the formation of this company, I exercised the option myself and bought the interest in the patents. This interest has since considerably increased in value. I now beg to state that I hand over to the new company the benefit of this purchase on the same terms, and will give the company such time as the directors may require to examine the various processes before deciding to take over the contract. The accompanying circular, with the statements in which I agree, shows the valuable nature of the rights and the importance of the patents, and the profits should be exceptionally large, having reference to the small amount of capital—namely, £7,000. I may add that Mr. J. W. Hughes, who has joined the Board of the new company, is the sole partner in the firm of Messrs. Hughes, Chemery, and Co. This firm has a large business abroad in connection with the metal, tinplate, and iron trade, and Mr. Hughes has had great experience in developing continental patents both for tinning and galvanising. He also has considerable experience in the steel trade, being a director of the highly-successful Harvey Steel Company of Great Britain, Limited. It has been proposed that I should join the Board, but I prefer to offer myself for election at the statutory meeting.

The second circular, bearing the signature of Mr. F. Dever-Summers, secretary (*pro tem.*) of the new company, and sent from 88, Queen Victoria-street, E.C., is substantially as follows. It is also addressed to the shareholders and creditors of Woodhouse and Rawson United:

During the last 18 months Mr. F. D. Leslie, the receiver for the debenture holders of Woodhouse and Rawson United, Limited, has been developing various inventions in which that company is interested. These are the subject of 12 letters patent and five provisionals, and are as follows:

(1) *W. S. Rawson's Electric (Metal) Pickling Patents.*—In the processes known as galvanising, tinning, leading, enamelling, etc, it is necessary to first remove the oxide, or, as it is called, the scale before dipping the pieces to be coated into the hot metal. This is called pickling, and at present is done by immersing the metal in strong acid, which has this disadvantage, that it not only removes the scale, but attacks the clean metal underneath. By the above invention the articles are placed in a weak solution of acid, a current of electricity is set up in the bath which rapidly removes the scale, and without the usual action on the surface of the clean iron or steel. Besides requiring less acid to remove the effect the removal, the waste acid is largely reduced, thus effecting a substantial saving and rendering the waste liquor easier to deal with. A royalty varying from 3d. to 1s. per ton will no doubt be obtainable, which ought to realise a large annual sum, as there are considerably over a million tons of articles per annum treated in the United Kingdom alone, and to over 400,000 tons of this the process is already applicable in its present stage of development. Further applications are being worked out. One of the largest manufacturers in the Black Country has just erected a plant, under license for this process. On account of its greater cleanliness the invention is specially adapted to the cleaning of wire and of plates for enamelling, and a modification of it has been successfully applied to the cleaning of brazed work, such as the joints, tubes, and other parts of bicycles. A firm of Birmingham bicycle manufacturers have had the process at work for nearly 12 months, and at the offices of the company can be seen a highly satisfactory written testimonial from them, both as to the quality of the work and the saving in expense. Hundreds of pieces have also been treated in London at highly remunerative prices.

(2) T *and* U *Smooth-Running Wheel Patents.*—These patents covers the inventions of Messrs. Aves, Bonn, and W. S. Rawson for combining permanent rubber cushions with a continuous T or U tyre in a wheel without felloes; in the case of the U-tyre it is fitted with wooden blocks to still further diminish shaking and noise. The invention is not fully completed, as the newest form—namely, the U-tyre with the wooden blocks for specially easy running—has still to be worked out. Mr. Bonn is manufacturing the latest form of wheels at his own works, and they will be ready within a week.*

(3) *W. S. Rawson and F. L. Rawson's Incandescent Gaslight Patents.*—This invention is for temporarily hardening mantles, such as those used in the well-known Welsbach incandescent gas burners, and rendering them less liable to fracture during their transmission from place to place. The invention has been fully worked out, and is thoroughly effective.

The following patents have also been worked out by Mr. W. S. Rawson:

(4) *W. S. Rawson and R. Heathfield's Galvanising Patents.*—These patents are for galvanising or covering with zinc in a cold state, by electro-deposition, iron and steel articles which at the present time are galvanised by being dipped in molten zinc, which is a very wasteful operation. Galvanising by the hot process divides itself into two branches: the first for plates and wire, where a certain amount of the unnecessary zinc can be wiped off and used again; the second for articles, such as screws, etc., where this is impossible. In the hot process far more zinc is put on than is necessary; by the above new cold process any given quantity or thickness of zinc can be uniformly distributed by electro-deposition over the surface of articles, however small, thus enabling many kinds of work to be treated which at present cannot be covered with zinc The saving in cost is large, as, beside the above gain, no oxide or dross is formed; and, further, when the plant is standing there is no waste of fuel or metal as at present, and the large quantity of muriate of ammonia, now used as a flux, is entirely saved. The present cost of hot galvanising varies from £2. 15s. to £4. 10s., and in special cases as much as £6 per ton, whilst by the new process the cost is estimated to be only from 25s. to 45s. per ton. Not only is the zinc far more evenly distributed, but some classes of work can now be coated which previously had to be left bare, and as it is a cold process, the iron or steel is not deteriorated by immersion in molten metal as in the hot process. Half a million tons per annum is a very moderate estimate of the articles capable of being treated by this process in the United Kingdom alone, of which at least 50,000 tons belong to the second branch mentioned above. One of the largest manufacturers of the latter class of work in Birmingham has erected a small trial plant capable of turning out about half a ton per week, which has been at work about two months with results even more satisfactory than was anticipated. Numerous applications have been made with regard to the use of the process for various kinds of work; for instance, by one of the leading firms of telegraph fitting manufacturers for a plant up to 30 tons per week, and by two large tube manufacturers turning out between them 20 to 30 tons per week of galvanised fittings. An application has also been received from the Continent for its use in connection with important military work, for which experiments already carried out have proved it to be particularly suitable. One of the principal railway companies has for some time past been making tests on the suitability of the work for certain railway fastenings, which, up to the present, it has not been possible to galvanise. The directors believe that one part of the galvanising patents will be usefully employed in the electro-plating industry in connection with other metals than zinc and negotiations between the patentees and one of the largest firms of electro-platers in England tend to confirm this.

(5) *W. S. Rawson and R. Heathfield's Zinc Recovery Patents.*—Scrap galvanised iron, for which there is at present little or no use, is put into a bath and a current set up which causes the zinc to pass into the solution. From this solution the zinc can be caused to pass on to the surface of new work, where it is equal to the best virgin spelter. Spelter dross, of which there is an unlimited supply, can also be used, at a cost of over £3. 10s. per ton less than virgin spelter, which costs about £15 per ton.

(6) *W. S. Rawson and R. Heathfield's Electric Renovating Patents.* By this process it has been found that rusty scrap, such as bolts and nuts, the value of which is almost nominal, can be successfully treated at a very small expense and rendered almost equal to new work, provided the rust has not actually eaten into the metal. A testimonial with regard to the results of work already carried out can be seen.

The interests of Woodhouse and Rawson United in the first three sets of patents above mentioned are as follows: (1) metal pickling patents, 60 per cent. of English and foreign rights; (2) T and U wheel patents, one-third of English and foreign rights; (3) incandescent gaslight patents, the entire English and United States rights.

Mr F. L. Rawson has for some time been negotiating with Mr. Leslie, endeavouring to save the most valuable assets of that company for the shareholders and creditors, and on the 14th ultimo he made, with the approval of the Court, an agreement with him to acquire the above interests for the sum of £1,500. This purchase, by agreement dated the 16th instant between himself and this company, he now hands over to this company without any profit to himself, he being only paid his out-of-pocket payments and expenses in connection with the above. With the exception that in the renovating process one of their patents is used, Woodhouse and Rawson United have no interest in the latter three sets of patents, Nos. 4, 5, and 6, which are owned by Mr. W. Stepney Rawson and Mr. Richard Heathfield; but in order to help the shareholders and creditors of Woodhouse and Rawson United, Mr. F. L. Rawson obtained the consent of Mr. W. S Rawson and Mr. Heathfield some time since to give this company, when formed, a 10 per cent. interest in the English patents, together with the option referred to below. These, the directors believe, are of great value. The option above mentioned is an option of taking out the various foreign patents of Mr. W. Stepney Rawson and Mr. Richard Heathfield (with the exception of those for the United States)—that is to say: (4) the galvanising patents; (5) the zinc recovery patents; (6) the electric renovating patents, and acquiring for the sum of £2,500 a 40 per cent. interest in the same, together with (7) the sole right of treating, or licensing others to treat, old material by the renovating process in the United Kingdom, taking one-fourth of all profits made therefrom; and (8) the sole right of galvanising job work in London, subject to the payment of a royalty of 10s. per ton to the patentees.

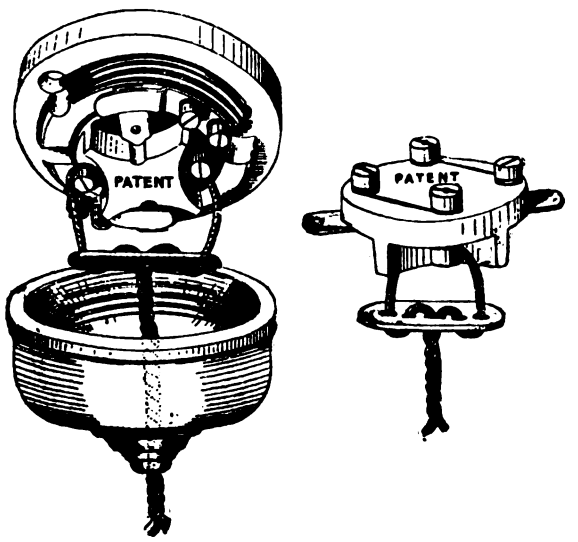
* Mr. Bonn has since written to the directors to say that he has completed his work, and that he has not the slightest hesitation in saying that the wheel will be a great success.

Digitized by Google

Mr. F. L. Rawson having, in order to secure the benefit of the option, exercised it himself by agreement with R. Heathfield and W. S. Rawson, dated November 21, 1894, and has arranged with the directors that this company shall have 14 days after the date of allotment for deciding whether they will take it over, on the same terms as paid by him. They are having the processes Nos. 4, 5, and 6 reported upon by an independent expert, and before finally deciding they will hold the statutory meeting of this company and lay the result of their investigations before the subscribers. It is not intended to confine the operations of this company to working the above patents. Woodhouse and Rawson United and its predecessors have for many years carried on, under Mr. F. L. Rawson, the business of developing and placing the patents of inventors and it is believed that this department has been always well and carefully managed. This class of business will be continued by this company. A detailed report has been made with reference to all the patents (except the wheel patents), and many of the statements herein are based thereon. The report itself can be seen at the offices of the company by any intending subscriber. No contracts have been entered into by this company except that of the 16th inst. mentioned above, which can be seen at the offices of the company. On October 16, 1893, Mr. F. D. Leslie made an agreement with Messrs. R. Heathfield and Son, whereby they agreed to act as agents for the licensing and dealing with the metal pickling patents, receiving therefor 10 per cent. of the profits The benefit of this agreement the company takes over. By agreement dated August 22, 1893, between Mr. F. D. Leslie and Mr. W. S. Rawson, the latter undertook the working out and development of the pickling patents at a moderate salary and 30 per cent. of the profits made. The company has the option of taking over this agreement. Failing the taking over of the agreement and the payment of the salary, Mr. W. S. Rawson will become entitled to an additional 15 per cent. of the net profits from the pickling patents. Sundry agreements with regard to the working of the inventions on royalty and defining the interests of the inventors between themselves have been made, which may be considered contracts within Section 38 of the Companies' Act, 1867 It is obviously undesirable that particulars of these should be given, and subscribers shall be deemed to have waived any further compliance with the said section. The capital of the company is 50,000 shares of £1 each, of which 7,000 are now offered for subscription to shareholders and creditors only of Woodhouse and Rawson United, Limited. The directors have sent in applications for 1,000 shares.

NEW DETACHABLE DOUBLE-POLE CEILING ROSE.

The accompanying illustrations, which represent a new ceiling rose brought out by Messrs. Cutting Bros. and Co., of Derby,



clearly show the advantages of this article. It will be seen that the construction of the rose, which is of the double-pole detachable type, allows of good connections being made in the workshop and easily examined and tested before erection; whilst at the same time all flexible pendants can be readily made exactly the same length, a matter of some importance in economy of labour when several pendants are placed in the same room. Among the advantages claimed for this ceiling rose may be mentioned that it affords a high insulation; that pendants connected with it can be removed in a moment, and replaced by the most inexperienced; that as the movable part is enclosed, and as there is no external metal work, the rose fully meets the requirements of the fire offices; and that it is specially adapted for shop window illumination or for other positions where lamps require frequent removal. The ceiling rose is provided with the company's adjustable cord grip, which it is stated will sustain any weight to the breaking of the cord without in the least disturbing the electrical connections.

CABLE REPAIRING.

We have been favoured with a copy of a Boston paper bearing the date of December 10, 1894, and containing a report of an interview which a representative of that paper had with Captain S. Trott, of the "Minia." The following extracts will be read with interest:

"This business of cable repairing," Captain Trott said, "is a science in itself. It would take hours to explain the thing thoroughly. You have asked me several questions, none of which are easily answered. You spoke of anchoring at sea. We do not anchor. To start with, supposing we are ordered to repair some break. We get the location as near as possible from those on shore, and proceed to the spot. We then lay about and place a buoy in position. The ship is kept under steam while we are there, and we keep our position as well as possible. We then take soundings to see what the bottom is like, and then drag for the cable with a grapnel until we hook it. Mind you, if the cable is in deep water that cannot be done. You cannot hook it and pull it up, because there is not slack enough to bring a bight to the surface. The cable, therefore, must be cut or broken unless we can get near enough to the break and pull up one end. Now, all this sounds very easy while I am telling you about it, but when you come to do the thing it is a different matter entirely. Allow me to give you an example. In July, 1893, one of the Anglo-American cables—the company I am employed by—broke. At the time I was out repairing one of our cables, one of the oldest by the way, having been laid in 1869. After completing my work I went to England for more cable to repair another break. When we got part on board our 1874 cable broke (you see we name our cables by the year they are laid), and another ship was hired to go out and repair it. She took the 100 miles of cable destined for us, half of which we had on board. We had to remain in England until another 100 miles were manufactured for us.

"In the meanwhile the 'Calabria,' double the size of us, had gone to repair the 1874 cable. She started in July, and was over 100 days at it. Once during that time she lifted one end, spoke the shore, and spliced one piece of new cable. When they commenced to pay out the cable broke, and, if my memory serves me right, it was on board ship. They lost it, and never recovered it again for that year. It sunk in 2,400 or 2,500 fathoms of water. There's one example for you. In October I was in St. John's and was ordered to proceed to England, I having told the manager that it was impossible to recover the cable that year. The 'Calabria' also went to England, the manager having agreed to what I said. All they had done was to break pieces off. This summer we were ordered to do the work and we did it. It has been our summer's work. Beyond doubt it was one of the most important ever accomplished."

"You are right, captain," an officer broke in; "and if you have too much modesty to say anything, I have not. They sent Captain Trott," he exclaimed, "because he never in all his life has failed to accomplish anything sent on."

"Well, that's neither here nor there," resumed the captain. "We were in lat. 49.50 and long. 40.30, so that'll give you some some idea of where we lay. We went to work in May, about the 20th, and it took us till nearly the end of July before we had completed the work. We had a lot of nasty weather, and one of the greatest difficulties I ever encountered, and one that I had least expected, was a strong stream running to the north-east. We, however, managed to complete the work, and that's all that need be said about it. The 'Faraday,' I learn, has put into Penzance, England, within a week. She was on one of the Gould cables, which is leased by the Western Union. She was working in long. 40, somewhat further south than we were. She failed. Like the 'Calabria,' she got one end, and that's all. They wanted me to take that job, but I was of the opinion that it could not be successfully performed. I have been engaged on different cables lately, and have just finished work on the Duxbury cable."

LEGAL INTELLIGENCE.

GLOBE DEBENTURE SECURITIES CORPORATION, LIMITED, v. ELMORE'S FOREIGN AND COLONIAL PATENT COPPER DEPOSITING COMPANY, LIMITED.

Mr. Justice Chitty, on the application of the plaintiffs, being debenture-holders of the defendant company, has made an order appointing Mr. C. W. Grimwade receiver of the property of the company comprised in the debenture security.

BURROWS v. PRIESTMAN BROS., LIMITED.

This was a debenture-holder's action relating to the company who manufacture oil-engines. Messrs. Watson and Hodson have been appointed receivers and managers. It was stated that a meeting was being held by shareholders to consider the advisability of winding up the company voluntarily.

PREFERENCE SHARE QUESTION.

In the Chancery Division on Saturday, Mr. Justice Romer dealt with a summons on behalf of Mr. Henry Percy Hope asking to have his name removed from the list of the members of the Electric Construction Corporation, Limited, and the list of contributories

Digitized by Google

in respect of 44 preference shares in the company. The applicant's case was, in the first place, that he had never made any application for the shares. That was not disputed, but Mr. Courtney said there was a tacit understanding amongst the directors, of whom Mr. Hope was one, that they would take a certain proportion of preference shares. The understanding in this particular case appeared to be that at a meeting of the Board, at which Mr. Hope was not present, the chairman said he supposed every director would take a fair proportion of shares. No director said he would not, and that was what was relied on as the tacit understanding that Mr. Hope, who was not there, would do so. The second point was that it was suggested that a letter of allotment was sent to Mr. Hope and that he did not return it. It was doubtful, it was contended, if such a letter was sent, and certainly Mr. Hope never received it. And further, though there had been several calls made in 1892, no notice was sent to Mr. Hope and he never paid any of them, or knew that his name was on the register until after the winding up in 1893, when the liquidator wrote to him. These facts were not disputed by Mr. Theobald, who appeared for the company, and his lordship thereupon directed that the register be rectified by the removal of Mr. Hope's name, and ordered the liquidator to pay the costs.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Saint-Dié (Vosges, France).—The Municipality invite tenders by February 1 for the concession for a central electric light station for the town.

Louvain (Belgium).—Tenders are invited by February 1 by the local authorities at the Hotel de Ville for a concession for an electric tramway from the railway station to the Grand Place, Louvain.

Newport (Mon.).—Tenders are invited for complete electric light installation for the Museum and Art Gallery, Dock-street, in accordance with plans and specifications, which may be seen upon application to Messrs. Swash and Bain, architects, Friars-chambers, Newport.

Lisbon.—Tenders are invited by 31st inst. for telegraphic apparatus and porous jars by the Royal Portuguese Railway Company, of Lisbon Particulars are obtainable from the bureau of the Compagnie Royale des Chemins de Fer Portugais, 28, Rue de Châteaudun, Paris.

London, E.C.—The County of London and Brush Provincial Electric Lighting Company invite tenders for the erection of central-station chimney shaft and other buildings at Oak Wharf, City-road, E.C. The plans, etc., can be seen at the offices of Mr. C. Stanley Peach, 8, John-street, Adelphi. Tenders must be sent in not later than February 4.

Manchester.—The Moss Side School Board invite tenders for the installation of the electric light in their schools in Princes-road, Moss Side. Plans, etc., may be obtained from Mr. S. V. Clirehugh, A.M.I C E., Temple-chambers, Brazennose-street, Manchester, on and after 28th inst., on payment of £1. 1s., which will be returned on receipt of *bonâ fide* tender. Tenders are to be sent by Wednesday, February 6, to Mr. W. E. Rowcliffe, clerk to the Board, 30 Cross-street, Manchester.

RESULTS OF TENDERS.

Southport.—The tender of Messrs. Morster and Wright, of Southport, has been accepted for bricklayers' labour for building walls at the electricity works with bricks set in Portland cement, at 4s. 6d. per cubic yard.

BUSINESS NOTES.

Woking.—A dinner has been given at the Masonic Hall by Messrs. New and Mayne to their employés.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,670.

Taunton.—The borough accountant states that loans have been sanctioned for the electric light works amounting to £5,000.

Bedford.—The Corporation have under consideration the question of extending the mains, there being an increasing demand on the part of private consumers.

West India and Panama Telegraph Company.—For the two weeks ended January 15 the receipts show a decrease of £354 as compared with the corresponding period of 1894

Croydon.—The High-street Special Committee of the Town Council have been instructed to obtain tenders for wiring and supplying electric light fittings for the Town Hall.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 20th inst. amounted to £900, as compared with £656 in the corresponding week of last year.

St. Pancras, N.W.—The Electricity Committee formally reported to the Vestry last week that Major Cardew had held an enquiry respecting the recent explosion, and that he would report later.

New Showrooms.—Messrs. Swinburne and Co., of Teddington, announce that they have now opened a showroom and offices at 66, Victoria-street (2, Prince's-mansions), S.W., where all communications should be addressed.

Copper.—The stocks of copper in England and France fell from 50,764 tons on December 31 to 50,267 tons on January 15, and the amount advised from Chili and Australia is 100 tons less, there being the decrease in the visible supply of 597 tons.

New Rubber Company, Limited.—This Company has been registered, with a capital of £35,000 in £1 shares, to carry on business as manufacturers of and dealers in rubber, guttapercha, and other elastic substances, and to produce and use electricity.

New Swindon.—The Town Council have referred to the Streets and Lighting Committee the question of appointing a committee to deal with the question of electric lighting. The names of Mr. D E. Marsh, Mr. Churchward, Mr. Deacon, and Mr. Protheroe have also been added to the committee.

Cardiff.—The electric light in the Town Hall buildings was switched on for the first time on Thursday of last week, on the occasion of the Mayor's banquet. The work has been carried out by Messrs. Fergus and Co., of Mount Stuart-square, Cardiff. There are 400 lamps, which are controlled by a main switchboard.

City and South London Railway.—The receipts of the Company for the week ended January 20 were £996, against £947 for the corresponding week of 1894, or an increase of £49. The total receipts for the current period of the present half-year are £3,001, against £2,888 in the corresponding period of 1894, an increase of £113.

Huddersfield.—It was mentioned at a recent meeting of the Town Council that in January, 1894, the number of consumers of the electric light was 89, with 8,229 8-c.p. lamps connected; in January, 1895, the number of consumers was 214, with 15,342 8 c.p. lamps, or an increase of nearly 7,000 lamps in the 12 months.

Buxton.—Trunk line telephonic communication has now been established from the Buxton Post Office to Manchester. The construction of the line and the fixing of the switchboard has been carried out at Buxton under the supervision of Mr. J. E. Owens, Derby, whilst the Manchester portion of the work has been carried out by Mr. T. Hughes.

Maidstone.—The Town Council last week postponed to the next meeting a resolution moved by Mr. Morling that the Council should endeavour to dispose of the electric lighting order by tender, the conditions to be settled by the Electric Lighting Committee. Mr. Morling moved the resolution in order to stir up the Electric Lighting Committee.

Sunlight Incandescent Gas Lamp Company, Limited.—This Company has been registered, with a capital of £15,000 in £5 shares, to carry into effect an agreement made with L. Oliver, and to carry on business as manufacturers and dealers in lamps, and all materials in connection with gas fitting and gas lighting, and appliances for electric lighting.

Southwark.—The St. George's (Southwark) Vestry have decided to ask the Board of Trade not to sanction large transformer-chambers in the public highways, such being regarded as dangerous. This is, however, a little late in the day, the Board of Trade having already given permission for the construction of such chambers, as stated in our last issue.

Paddington, W.—The Electric Lighting Committee of the Vestry reported last week that having considered the application of Mr. Whiteley to fix electric lamps outside his premises in Queen's-road, they instructed the surveyor to ascertain certain particulars from Mr. Whiteley's engineer, and such particulars being satisfactory, the application had been granted.

Douglas.—A public meeting was held at Douglas on Monday to consider the advisability of establishing a tram service to the upper part of the town. A resolution was passed declaring that, owing to the depreciation of property in the upper part of Douglas, the time had arrived for a tramway service; that the Town Commissioners be called upon to take immediate steps to carry it out; and that the district benefitting contribute on the betterment principle towards any loss.

Coventry.—The Electric Light Committee of the Corporation recently advertised for tenders for the supply of meters of various sizes. Messrs. Chamberlain and Hookham, Limited, Birmingham, sent in the lowest tender for 60, and the committee recommended its acceptance. The price was £270. 10s., and £20. 14s. for testing the meters. Alderman Hill moved at a meeting of the Council the acceptance of the committee's report. Mr. West seconded, and the Council approved unanimously.

Blackburn.—The Gas Committee of the Blackburn Corporation recently appointed Mr. A. S. Giles borough electrical engineer. The work at the central station, which has been carried out under the superintendence of Mr. E. M. Lacey, who was appointed consulting engineer in September last, is nearing completion, and the Corporation expect to be in a position to supply current in the course of the next two or three weeks. Applications for upwards of 1,800 lights have already been received.

Luminous Enamel.—The Luminous Enamel Syndicate, of 37, Cursitor-street, Chancery-lane, E.C., have sent us a copy of a circular referring to their luminous enamel. They claim that when applied to incandescent lamps this enamel entirely hides the filament, renders the light a bright white and soft to the eyes, and that it increases the illuminating power of the lamp. The enamel is made in different colours, and it can be put on in ornamental figures and flowers. The enamel is said to be also particularly suitable for arc lamp globes.

Edinburgh.—The second annual soirée and concert of the workmen of the Edinburgh and Leith Corporations Gas Commissioners were held a few days ago at Leith. Bailie Manclark (the chairman), referring to the electric light, said they were likely to have a

Digitized by Google

strong opponent in that. They would have to do their level best to turn out gas at the lowest possible price. Some of the larger consumers in Edinburgh were sure to go in for the electric light. They would require by mechanical stoking and water and oil gas to compete with electric light, and show there was nothing like gas.

Warning.—Messrs. Russell and Co. write to a daily paper stating that a man representing himself sometimes as a traveller of that firm and sometimes as a certain Russell, of Melbourne, has been ordering on their behalf or giving their name as a reference for orders for carriages, tobacco pipes, and fireworks. He does not appear in any case to have actually obtained any property or money, but, as the man is probably an impostor, Messrs. Russell and Co. state that it would be as well if the next firm on whom he calls were to detain him until the police had had an opportunity of making his acquaintance.

St. Luke's, N.—The attention of the Vestry was called last week by Mr. Leage to the state of the pavements in that part of the City-road where the electric lighting company are laying mains. He stated that the pavement was impassable. Mr. Pond and Mr. Walsh made similar complaints with regard to the condition of the parts of Central-street and Old-street. The surveyor remarked that there had been already five or six days' frost, in consequence of which the pavement works were suspended, as it would be useless to carry them on in such weather. The matter was left in the hands of the surveyor.

Dublin Tramways.—The Dublin United Tramways Company on Tuesday approved of the introduction of a Bill providing for the use of electric power on the Dublin street cars. The Chairman (Dr. Carte, J.P.) said they had examined the systems in use in Paris, Brussels, and Frankfort, and had come to the conclusion from what they saw that the days of horses in street cars were numbered. The electric system was better and cheaper, and they hoped that the Dublin Corporation would give them every assistance in introducing it. They believed, from what they saw, in the system of overhead wires, and they intended, if power were given and subject to the advice of experts, to introduce it on the Clontarf line.

Brighton.—The minutes of the Lighting Committee, presented to the Town Council last week, mentioned that at a meeting of the committee on December 31 a letter was read from Councillor Blaker requesting the committee to reconsider the question of lighting the Marine-parade by electricity, but it was resolved to inform Mr. Blaker that the committee saw no reason to withdraw their recommendation. The committee agreed to accept the offer of the successors of Latimer Clark and Co. to supply them with a repaired field-magnet coil for £40. At a subsequent meeting on the 7th inst. the committee approved plans showing the position of the electric lamps to be erected in Western-road, North-street Quadrant, North-street, and Old-steine.

Scarborough.—The Sanitary and Lighting Committee of the Town Council having considered the question of obtaining tenders for lighting certain streets with the electric light, have resolved that the town clerk be instructed to obtain a tender from the Scarborough Electric Supply Company for lighting certain streets with the electric light. The Electric Lighting Sub-Committee have presented a report from Mr. B. Drake, who stated that in accordance with instructions he had made a personal inspection of the Scarborough lighting station, and was pleased to say that he found it in a generally satisfactory condition. He recommended that another engine and fan should be provided as duplicate to the present one, for at present, if anything happened to either the small vertical engine or fan, the ventilation would not be maintained.

Sale of Plant.—On Wednesday, February 6, Messrs. Wheatley Kirk, Price, and Goulty will sell the electric lighting plant, instruments, arc lamps, transformers, cable, stores, etc., of the Brighton and Hove Electric Light Company, Limited, at the central lighting station, 48, Gloucester-road, Brighton. The plant comprises four Lowrie-Parker alternating, one Mordey-Victoria, six series-wound, one Ferranti, one Gramme, and other dynamos; water tank and purifier; four 50-h.p. undertype engines and boilers, by Fowler; four donkey pumps, by Pearn; shafting, 60 accumulators, switchroom appliances, test instruments; 19 Brush, Brockie-Pell, Kent, and Croggan arc lamps; about 20 miles cable; 166 Lowrie-Hall, E.C.C., Goolden, etc., transformers; fuses, switches, instruments, belting, loose tools, stores, office furniture, and other effects.

Bournemouth.—The Town Council last week adopted the report of the Electric Lighting Committee. The latter reported, with reference to the Bournemouth public purposes electric lighting license granted to the Corporation, that the Board of Trade had approved the system proposed to be adopted by the Corporation. The committee also recommended that the draft contract for the electric lighting of the Winter Garden should be settled by the chairman and town clerk before being submitted to the electric supply company for approval. The committee recommended that the Bournemouth Electric Supply Company should be asked whether there had been any alteration in the constitution of the company, involving a transfer of their undertaking, and whether the consent and approval required by Section 4 of the Poole Electric Lighting Order, 1891, had been applied for and obtained.

Wolverhampton.—A meeting of the Town Council has been held, at which Alderman Owen asked when the electric light would be ready. The Mayor replied that no member of the Council was more annoyed at the state of affairs than himself. When he said that their contracts were to have been completed by September 1, and that an extension of time was given, they might reasonably suppose the electric light would have been installed long before the present time. But it was absolutely of no use for the committee to take over the works until they were satisfactorily completed. It was absolutely essential that a complete test should be made for at least a week before they took over the whole of the delicate machinery and lighted the town. Arrangements had been made for tests, but they had not been completed. If those tests were satisfactory, the town would be lighted at an early date.

Sheffield.—The directors of the Electric Light and Power Company on Monday met their customers, and explained to them the causes that have led to the recent temporary interruptions of supply, and also to state the arrangements which are being made to prevent a recurrence of such mishaps. The explanations and assurances of Alderman Franklin, the chairman of the company, who was supported by Alderman Gamble, Messrs. George Senior, W. S. Laycock, and William Tasker (directors), and Mr. William Johnson (manager and secretary), were cordially appreciated. The new electric light plant laid down by the local company comprises a Willans compound engine running at 520 revolutions per minute, and coupled direct to a Wilson-Hartnell dynamo. The engine, with 95lb. of steam, gives 39 h.p. These engines are extremely economical in coal, a consumption of 13lb. of steam per indicated horse-power having been recorded.

Direct United States Cable Company.—The report of the directors for the six months ended December 31 last states that the half-year's revenue, after deducting out-payments, amounted to £38,342, as compared with £41,051 for the corresponding period of 1893, being a decrease of £2,709. The working and other expenses for the same period, including income tax, but exclusive of cost of repairs of cable, amounted to £19,024, leaving a balance of £19,318 as the net profit, making, with £1,031 brought forward from the previous half-year, a total of £20,349. Interim dividends of 2s. per share for the quarter ended September 30 and of 2s. per share for the quarter ended December 31 have been declared, and after setting aside £3,400 pending settlement of disputed accounts with other telegraph companies and £3,000 to the reserve fund account the balance of £1,807 on the revenue account has been carried forward.

Kingston-on-Thames.—The Town Council last week adopted a report of the Lighting and Market Committee, which contained the following: That Councillor Collins be appointed chairman of the committee for the ensuing year, and that Councillor Salmon be appointed vice-chairman. Tenders were opened for the supply of materials and work to be done at the electric lighting works with regard to the new boiler, and that of Mr. H. Barrett was accepted. It was resolved that in future a minimum charge of £2. 10s. per annum be made for current supplied, and a clause to that effect inserted in the agreements. The town clerk read a letter from the Artisans' Land Company, asking the Corporation to take the necessary steps for the efficient electric lighting of the new roads made, or proposed to be made, on their estate, as shown on plan, and for the supply of electricity for lighting and cooking purposes in houses on the same estate. It was resolved that the town clerk be instructed to enquire of the company if they are prepared to pay the cost of laying down the mains and erecting arc columns in such roads.

Eastern Telegraph Company.—The directors, in their report for the six months ended September 30 last, state that the revenue for the period amounted to £362,557, from which are deducted £97,533 for the ordinary expenses and £43,709 for expenditure relating to repairs and renewals of cables, etc., during the half-year. After providing £4,815 for depreciation of spare cable, £1,138 due to revaluation of currency assets, and £5,458 for income tax, there remains a balance of £209,902, to which is added £2,001 brought from the preceding half-year, making a total available balance of £211,903. From this balance there have been paid interest on debentures and debenture stock, dividend on preference shares, and two interim dividends of 2s. 6d. per share each on the ordinary shares. After carrying £4,860 to the reserve fund for maintenance ships, there remains a balance of £59,175, which is carried forward to the next account. The revenue includes £22,687 dividends for the half-year upon the Company's shares in the Eastern and South African, the Black Sea, the Direct Spanish, and the African Direct Telegraph Companies.

Hampstead.—The Vestry last week adopted several recommendations of the Electric Lighting Committee. One was that Mr. H. W. Christmas, solicitor for Mr. R. Scarlett, of Heath-street, should be informed, in reply to his letter on the subject of the transformer-chamber recently built in the footway opposite his client's premises, that the Vestry could see no reason to offer any compensation in the matter. A second was that two partitions should be put up in the coal bunkers for the purpose of further utilising the space at an estimated cost of £5. 10s.; that a light two-wheeled hand-truck, for carrying tools and materials for house connections, be obtained at an estimated cost of £7; that the horizontal shafting over the top of the boilers be fenced in according to the requirements of the Government factory inspector at an estimated cost of £5. 10s.; and that the offer of Messrs. Radford and Co. to supply 50 tons of Derbyshire coal at 13s. per ton should be accepted. The committee appointed to inspect and approve of the fittings to be used in the installation in the Vestry Hall reported that they had inspected the fittings supplied by Messrs. Verity and Sons, and passed them as satisfactory.

Church-Lighting.—The vicar and churchwardens of St. Peter's Church, Eaton-square, are to be congratulated on their decision some time back to light St. Peter's Church by electricity, and at

Digitized by Google

the same time to clean and recolour the interior. The electric light has now been put in, and the arrangement of the new illuminant is eminently successful. It is a feature of the scheme to utilise the reflecting power of the light colours on the surrounding surfaces in order to obtain an equal diffusion of light, and to avoid an otherwise prodigal waste of lights, whilst at the same time hiding as much as possible the actual lights from the direct vision of the congregation. The illumination of the architectural features and beautiful mosaic work in the sanctuary is particularly pleasing, as there are no lights actually seen to distract the attention or weary the eyes. When the additions and alterations to the edifice—which are in progress—are completed there will be some 260 lamps fixed, replacing some 640 gas burners previously in use. The scheme of lighting is from the designs of Mr. W. Howard Tasker, M.I.E.E., of Pembroke-road, Kensington, who prepared the plans and specification, and under whose supervision the work was carried out. Messrs. Moody Bros. secured the contract.

Mallow.—When the Town Commissioners met on Monday, Mr. Harold mentioned a matter which he considered was of utmost importance He complained, as a town commissioner and representative of the ratepayers, that the Mallow Gas Company, who traded under the appellation of the New Mallow Gas Company, were in no way better than the old. They (the Commissioners) had often made complaints against the old company, but they had double the number against the new. He (Mr. Harold) wished to have the Commissioners direct their clerk to write to the gas company on the matter. He also wished to give notice that at the Commissioners' next meeting he would bring forward a scheme for the purpose of lighting the town by electricity, and he would show that they could do it with water as a motive power. He believed the cost would be considerably less than it was at present, and they would try and form a little company for that purpose. What he wished to have the clerk write to the company was that unless they settled the matter complained of, they (the Commissioners) would form themselves into a company and light the town by electricity. After some discussion on the matter, the clerk was directed to communicate, in compliance with Mr. Harold's suggestions, with the gas company.

Newark.—The clerk to the Rural District Council read to the latter on Tuesday an application from the gas company for consent to their provisional order. In doing so, he remarked that if they put all these powers in the hands of the company they might monopolise the supply of electricity. He thought there could be no objection to the extension, but the section relating to the supply of electricity was open to objection. Alderman Hole said he was not sure that it would be wise to sanction the extension. Their Parish Council had ordered the letter to lie on the table, and they had done something of the same kind in Balderton. There was an idea that having the supply of all these places would increase the prospective value of the works. As they were aware, negotiations were going on with the Newark Corporation, and if they agreed to this extension, they virtually cut out the other side from setting up gasworks, or from arranging a supply of their own if they wished it. He thought they should stand a much better chance of being dealt with by the Corporation than of being dealt with by the present company. The Parliamentary Committee of the County Council met a few days ago, and they were going to oppose it, and it would be safe for them to do the same. He proposed that they object to give their consent to the provisional order. Mr. Whitaker seconded the proposition, which was agreed to.

Anglo-American Telegraph Company.—The report of the directors for the past half-year states that the total receipts from July 1 to December 31, 1894, including the balance of £1,173 brought forward from the last account, amounted to £148,837. This sum, however, is subject to revision, as the financial result of the judgment given in favour of this Company against the Paris and New York Telegraph Company cannot yet be determined. The traffic receipts show a decrease of £6,948 as compared with the corresponding period of last year. The total expenses of the half-year, including the repair of cables, etc., as shown by the revenue account, amounted to £55,851, being a decrease of £3,399. The directors, under the powers conferred upon them by the articles of association, have, before declaring the net profits, set apart the sum of £12,000 to the renewal fund, leaving a balance of £80 985. Interim quarterly dividends of 9s. per cent. on the ordinary stock and 18s. per cent. on the preferred stock were paid on November 1 last, leaving a balance of £49,485, out of which the directors recommend the proprietors to declare final dividends of 14s. per cent on the ordinary stock and £1. 8s. per cent. on the preferred stock, making a total distribution for the year of £2. 2s. per cent. on the ordinary stock and £4 4s. per cent. on the preferred stock, leaving £485 to be carried forward to the next account.

Morecambe.—The annual meeting of the ratepayers of the Sandylands division of the parish of Heysham was held recently at the Cumberland View Hotel, for the purpose of transacting ordinary business and considering the proposed electric lighting question of the Sandylands district. The inspectors' report was read as follows: "When the ratepayers at our meetings a few months ago decided to adopt the electric light for public lighting of the Sandylands district of the parish of Heysham it was stated that the business was practically accomplished. We, your inspectors, regret to have to report that subsequent events have proved that it was not so. Your inspectors made a contract with the Morecambe Electric Light and Power Company according to which you were to have had the light on March 5. You all know that, although the lamps have been erected by the company, we have had no electric light, yet your inspectors and late secretary did everything that could be done to induce the company to complete the contract. They have had a great number of meetings and many interviews with various persons and a voluminous correspondence and law proceedings without the desired result. We cannot discuss the case in public meeting until after judgment, but our solicitor and counsel are of opinion that we have a good case. We, however, suggest that you appoint six of your number to confer with us respecting the matter. We expect to have public lighting in a few weeks now." Some ratepayers were elected to confer with the inspectors respecting the action pending against the Morecambe Electric Light and Power Company for alleged breach of agreement to supply the Sandylands district with electric light. After some discussion it was decided to adjourn the meeting until some future date, when the inspectors and the above-appointed gentlemen would report on their negotiations with the electric light company.

Bath.—The Town Council last week discussed at some length the present position of electric lighting in the town. Alderman Sturges, chairman of the Lighting Committee, moved a resolution that the application of the electric light company for a provisional order should not be consented to, but that the authority apply to the Board of Trade for an order. He explained that the committee had consulted Mr. Medhurst. There was a large meeting of 15 or 20 members of the committee present, and they were quite unanimous in their opinion that it would be advisable to take the step they proposed. The advice given them by Mr. Medhurst was to this effect: "It's no use for you to rest upon saying that you do not wish them to obtain a provisional order The Board of Trade will say you must allow either the company to obtain it or obtain it yourselves; you must not act the part of the dog in the manger, that you can't do it yourselves and won't let anybody else do it." The Council must either go backwards or forwards. He had previously pointed out that the company had a license for seven years, and only four had elapsed, but Mr. Medhurst said the Board of Trade would not look at that as sufficient reason for refusing the provisional order, although they might think it very strange for the company to apply now. With regard to their application for a provisional order, Alderman Sturges pointed out that the Board of Trade naturally leaned to the authority, and quoted a similar case in which the authority were granted the provisional order and the company afterwards went to them and gave them a bonus of £300 for it. He hoped they would not allow the company to take the place which they themselves ought to occupy. It was for them as an authority to set themselves against great monopolies. The gas company was a great monopoly, and there was no doubt about it, if they were the owners of the gasworks the rates of the city would be lighter. There was a general public feeling in favour of these things being in the hands of the Corporation. What was to follow after they had obtained the provisional order was, of course, a thing to be decided upon later. They might either work the station themselves or lease to the company and get a bonus that would be remunerative to the public. Mr. Stone formally seconded the resolution, which after some discussion was adopted.

Messrs. Felten and Guilleaume.—This firm, of Carlswerk, Mulheim-on-Rhine, who are represented in this country by Messrs. W. F. Dennis and Co., of 11, Billiter-street, E.C., have been very busy during the past year in their cable factory, and have supplied high and low pressure cables for numerous electric light central stations, as well as for electric tramways. Among these may be mentioned for Frankfort-on-the-Maine, Hamburg, Pforzheim, Sigmaringen, Neustadt on-the-Haardt, Donauschingen, Salzungen, Liège, Saragossa, and Madrid, the total length amounting to about 400 miles. Besides the above, the firm have secured the following contracts for supply of the cables for Dresden, Stuttgart, Munich, Frankfort-on-the-Maine, Hamburg, Ulm, Aix-la-Chapelle, in all about 600 miles. Apart from electric light cables, Messrs. Felten and Guilleaume have again been favoured by the Imperial German Post Office with numerous contracts, amounting to several hundred miles, for telegraph and telephone cables, and have laid a new telegraph cable to the Isle of Borkum, consisting of about 20 miles underground and the same length of submarine cable. The firm have during the past year continued to make strenuous efforts towards the adoption of their paper and air-space telephone cables which, wherever supplied, have been highly appreciated. Some of the great advantages are their high insulation resistance and low capacity, no other cable, it is claimed, yielding such a low capacity. The same system is also being advantageously used for telegraph and electric light cables. The firm's bronze wires, especially the double bronze wire, meet everywhere with the greatest satisfaction, and they have withstood frequent snowstorms better than any other material hitherto used, the lines having hardly been damaged at all. The bronze wire as well as paper and air-space telephone cable are used for the telephone line from Madrid to Barcelona. In addition to the many articles made by Messrs. Felten and Guilleaume, they have now taken up the manufacture of the so-called "Salamander wire," the first and only strictly fireproof-insulated wire produced. The covering of this wire, it is stated, will not burn when exposed to a flame, and the conductor can be heated to the melting point without igniting the insulation. The rope factory has also been very busy with orders for ropes of ordinary construction for all purposes. Their locked coil ropes are also gaining the favour of interested circles more and more in consequence of the better results they have given over ordinary types. Another towing-rope of about 20 miles, in one length, has also been supplied for the Rhine. The firm's Antwerp exhibits have been awarded four grand prizes.

Edison and Swan United.—An extraordinary general meeting of the Edison and Swan United Electric Light Company will be

Digitized by Google

held at the Cannon-street Hotel on Tuesday, February 5, at half-past twelve o'clock, to consider and, if approved, to pass the following resolutions, which, if passed, will be submitted to a subsequent general meeting for confirmation as special resolutions: That article 10 be repealed, and the following article substituted: "10. The instrument of transfer of any share in the Company shall be on the usual common form, under seal, and be executed both by the transferor and transferee, and the transferor shall be deemed to remain the holder of such share until the name of the transferee is entered in the register book in respect thereof." That the words "or stock" be omitted from article 11. That the following words be inserted at the end of article 16: "And that no call shall exceed one-fourth the nominal amount of a share, nor be made payable within two months after the last preceding call was payable." That in article 20 the words "not fully paid up" be inserted after the word "shares." That article 41 be repealed, and the following articles substituted therefor: "41. Seven days' notice of any general meeting (exclusive both of the day on which the notice is served or deemed to be served, and of the day of the meeting) specifying the day, hour, and place of the meeting shall be given to the members in manner hereinafter mentioned, or in such other manner as may from time to time be prescribed by the Company in general meeting, but the non-receipt of such notice by any member shall not invalidate the proceedings at any general meeting." "41a. The notice convening an ordinary general meeting shall state the general nature of any business intended to be transacted thereat, other than declaring dividends, electing directors and auditors, and voting their remuneration and considering the accounts presented by the Board, and the reports of the Board and the auditors. The notice convening an extraordinary general meeting shall state the general nature of the business intended to be transacted thereat." That article 59 be repealed, and the following article substituted: "The qualification of a director shall be the holding, in his own right, of not less than 200 A or B shares. A first director may act before acquiring his qualification, but shall in any case acquire the same within one month from his appointment, and unless he shall do so he shall be deemed to have agreed to take the said shares from the Company, and the same shall be forthwith allotted to him accordingly." That in article 65, clause (*c*) the words "or in loans upon the security of" be inserted before the words "its own shares." That the following words be inserted at the end of clause (*f*) of the same article: "Provided that without the sanction of a general meeting the Board shall not raise or borrow any sum of money which will make the amount raised or borrowed and then outstanding exceed £200,000." That the following words be added at the end of article 94: "And a copy of such balance-sheet and account shall be sent seven days before the general meeting to each member entitled to the same."

Messrs. Drake and Gorham.—During the past year this well-known firm have made considerable progress, work having been carried out by the firm or partners for the following clients: the Duke of Devonshire; Lord Houghton; Army and Navy Stores; Lord Gosford; Scarborough Corporation town-lighting; Earl Derby; Marquis of Londonderry; Baron Schröder; Baron de Knoop; Sir Frank Lockwood; Duchess of Montrose; Lady Wynne; Greenway House, for Mr. T. B. Bolitho, M.P.; The Lodge, for Mr. Felix T. Cobbold; Mr. Victor Cavendish; Lady Sitwell; The Manor House, for Mr. H. T. Alton; Etherington Hill, for Mr. E. Janson; LeCourt, for Mr. Heath Harrison; The Priory, Rugeley; Sutton House, for Mr. Andrew Jameson; Abney Hall, for Mr. Watts; Testwood, for Captain Beaumont; Sir Gervas Glyn, Ewell; Mr. J. T. Smithes, Eveley; Mr. R. Clifford Smith, Ashford Hall; Mr. T. Howland, Amersham; Right Hon. C. T. Ritchie, The Welders; Mr. C. Behrens, Holmacre; Mr. B. Pennington, Sydenham; Mr. V H. Nevill, Bramall Hall; Dr. Venn, Kemnal Wood; Mrs. Torrens, Eaton-square; Royal Geographical Society; University Galleries; St. George's Hospital (further extensions); Balliol College; Messrs. David Allen and Sons, printing works; the Manchester, Sheffield, and Lincolnshire Railway, London offices; the *Morning* offices; City of London College; borough of Richmond main sewerage works; Buenos Ayres and Rosario Railway Company; Exploration Company; Mr. G. S. Harris; Mrs. Barbara Allen; Sir Vincent Barrington; Dr. Anderson (extensions); Mr. Pearse Gould; and Mrs. Ewart. The same progress is recorded at the Manchester and Scarborough branches, of which the following instances may be given: Lancashire Assurance Company; Brook's Estate; Haworth's Buildings; Mudie's Library; Adelphi Bank; Barton-arcade; Bridgwater Trustees; Muirhead and Sons (arc and incandescent lamps); Darbishire, Tatham, and Worthington; the Sun Fire Offices; Consolidated Bank; Brook's Bank, Blackburn; further extensions at Colonel Steble's; Masonic Hall; Sarony and Co.; Mr. J. Woodall; Dr. Dale; Dr. Horn; the Spa Theatre; and Mr. H. A. Johnson. The number of lights put in during the year equals about 40,000 of 8 c.p. The D.P. battery introduced some six years ago is steadily gaining in popularity, as contractors have found after trial that there are many advantages in their use, and the consequence is an enormous increase in the sale during the year. Hundreds of batteries are now in use all over the country, and many can be seen in daily work which have lasted for six years without repairs, and appear as good as new. Spring contact switches command a large sale in the trade, and most of the important manufacturers have taken a license for this type of switch. The earthing device has been supplied in large quantities to supply companies, and no case has yet occurred where it has failed to effect its purpose. There are now over 2,400 of these in daily use. The Cardew voltmeter has been remodelled by Major Holden, and a recording instrument made on these lines is rapidly growing in favour among central-station engineers.

Newcastle Tramways.—The Town Council last week discussed the report of the Parliamentary and By-Laws Committee with regard to the North-Eastern Railway Bill, 1895, and the Newcastle Tramways Provisional Order, 1895. The report with regard to the Railway Bill said it was proposed to widen on the south side the bridge which carries the company's line over the Forth Banks. The committee saw no objection to the Bill. With regard to the draft Tramways Provisional Order, the committee reported as follows: "That there be added to Clause 5 'or by any other mechanical power which may be sanctioned by the Board of Trade'; that Clause 6 be altered so as to read, "All Acts of Parliament and all by laws and regulations made by or with the approval of the Board of Trade for the time being in force relating to the use of steam or mechanical power upon the said tramways shall, so far as they are applicable for the purpose, extend and apply to the use on such tramways of the motive power by this order authorised'; that there be added to Clause 9, 'The repayment of all moneys borrowed under the provisions of this order shall be effected by equal yearly or half-yearly instalments of principal or of principal and interest." The report, so far as concerned the North-Eastern Railway Bill, was agreed to. With regard to the cable trams, Alderman Richardson wanted to know if, in his communication to the Council, Mr. Eustace Smith, as representing the newly-formed tramway company, had undertaken with the Corporation to adopt any other system, be it electrical or any other system, that could be worked in the future as efficiently and as cheaply as the cable system, as to the remainder of the tramways. The Town Clerk having read the letter from the lessees bearing on this subject, Alderman Richardson said he took it that the guarantee of Mr. Eustace Smith meant that the proposal of the lessees at present was to work the cable system upon the Westgate, Scotswood, and Byker routes for five years. The Town Clerk did not think their proposal meant anything of the kind. The lessees asked for those lines to be converted to cable lines, and asked for a lease of 21 years from the expiration of the present lease, which was really 26 years from now. The lessees then said the remainder of the present lines should be continued as horse lines for a period of, say, three years from the opening of the new cable lines. They asked that the cable lines be put down within two years. Then they said that, within three years from the beginning of the cable system, the Corporation should apply to them any form of mechanical traction approved by them as being as economical per car mile as the cable system in this city. They wanted the Corporation within three years of the opening of the cable lines on the Scotswood, Westgate, and Byker lines, to adopt some kind of mechanical traction approved by them for the remainder of the lines. In reply to a question, the Town Clerk said he thought "approved by them" meant by the Corporation. Alderman Hamond moved, "That this provisional order be not proceeded with in the ensuing Parliament." There was a letter, he said, sent to the Town Improvement Committee on the subject of the tramways from a firm at Chester. No report had been presented by the committee to the Council on that offer, although he understood that the firm was prepared to lay down a line and try the electric system in the city at their own expense. The Town Improvement Committee had treated the offer with contempt; they were afraid of the result, or they were indifferent to the interests of the public On this ground alone he was justified in making this proposition. Mr. Goolden seconded the motion, which was ultimately rejected, and the report was adopted.

Aberdeen and Telephony.—The Finance Committee reported to the Aberdeen Town Council on Monday that a letter had been submitted from the town clerk of Glasgow transmitting copy of a memorandum recently addressed by the Corporation of Glasgow to the Postmaster-General with reference to the agreements which the Postmaster-General proposes to enter into with the National Telephone Company, Limited, and the New Telephone Company, Limited. In their memorandum it was suggested that the Government should assume the working of the telephone system in the same way as the telegraph, and that if Government is not prepared to do so municipal authorities should, when they so desire, receive a license to undertake the telephonic service within the areas under their charge. If, however, agreements are to be made by Government with the telephone companies, the Glasgow Corporation submitted that due provision should be made for safeguarding the rights of municipal authorities as regards interference with streets and similar matters, and also for the protection of the public with reference to obligation as to supply, maximum charges, and maximum dividends. The committee recommended (*a*) that the Town Council should co-operate with the Corporation of Glasgow in pressing upon the Postmaster-General the views above indicated; and (*b*) that in the event of the Postmaster-General consenting to receive a deputation, in accordance with the request which has been made to him, the convener should be authorised to represent the Town Council. Treasurer Bisset, in moving the adoption of the recommendation, said the object of the Finance Committee was to assist other municipal corporations in their endeavour to get a more satisfactory settlement of the question with regard to the telephonic service. At present there was an agreement lying on the table of Parliament as to arrangements proposed to be entered into between the Postmaster-General and the National Telephone Company. Hitherto, the National Telephone Company had not had any legal standing in any district. They existed on suffrage, and the Town Council could put a stop to their operations if they cared to do so by simply refusing to allow them to cross the streets with their wires. The system of carrying the wires overhead was very unsatisfactory, and was objected to on many grounds. A Select Committee of the House of Lords had reported that it

Digitized by Google

should not be allowed to continue, and that any new license would be given only on condition that the wires were put underground. With a view to enabling the telephone company to carry out the recommendation of the committee, the Postmaster-General, in the agreement referred to, asked Parliament to confer upon the telephone company the power of entering streets and other property belonging to the different corporations and private bodies for the purpose of carrying on their operations. The treasurer was perfectly satisfied that they could not at this time of day allow such a thing to be done by a private company which was not subject to public control. The capital of the telephone company was close upon £5,000,000, and a very large proportion of that had been spent in buying up other companies and in buying up patents that had now expired, and were therefore of no value. The actual value of the property did not exceed £1,000,000. He spoke in favour of municipalities being granted a license to carry on the system, and pointed out that were something not done they would have to go on paying interest on five times the actual value of the property owned by the present company There were two alternatives. They might join with other municipalities in doing something to put an end to this thing, or they could allow the public to be fleeced as they had been fleeced in the past by paying heavily for a very inefficient service. A very efficient service could be given to the public for one-half of what they were at present paying. So far as they were concerned, in the meantime they had simply to agree to back up the other municipalities in their effort in the interests of the public, and they were perfectly satisfied the public could get a much better service than at present at a much lower cost. Bailie Edwards seconded the motion, which, after some discussion, was adopted.

PROVISIONAL PATENTS, 1895.

JANUARY 14.

856. **Improvements in telephonic transmitters.** John Harry Salter, 70, Chancery-lane, London.

867. **An improved electricity meter for registering the amount of current consumed on direct or alternating polyphase, triphase, or quadruplephase circuits.** Frederick John Beaumont and Frederick Hallows, 166, Fleet-street, London.

883. **Production of liquid ammonia by electricity.** Richard William Hill, 97, Newgate street, London.

884. **An electric alarm and detector of oxygen gas.** Richard William Hill, 97, Newgate-street, London.

890. **An electrical ballet.** Adolph Cannot, trading as A. H. Chamberlyn, 175, Strand, London.

JANUARY 15.

962. **Improvements in and relating to electric railways and apparatus therefor.** Carl Friedrich Philipp Stendebach, 18, Buckingham-street, Strand, London.

1000. **Improvements in and relating to conduit electric railways.** William Tasker Dulany, jun., and Oscar Fisher Shaw, 77, Chancery-lane, London. (Complete specification.)

1012. **An improved electrical device for lighting and extinguishing incandescent gas lamps.** William Phillips Thompson, 31, High Holborn, London. (Julius Bilfinger, Germany) (Complete specification)

JANUARY 16.

1085. **Improvements in electrical apparatus for lighting and extinguishing gas burners.** Axel Orling and Oscar Ehrenfried Wollert, 4, South-street, Finsbury, London.

1088. **An improvement in safety fuses for high-tension electric currents.** Siemens Bros. and Co., Limited, and Francis Hird, 28, Southampton buildings, Chancery-lane, London. (Complete specification.)

JANUARY 17.

1116. **Improvements connected with boats and vessels propelled by electricity.** Robert McLauchlan McDonald and Alexander McDonald, 70, Wellington-street, Glasgow.

1117. **Improvements in electric batteries.** Robert McLauchlan McDonald and Alexander McDonald, 70, Wellington-street, Glasgow.

1120. **Improvements in telephone circuits and apparatus appertaining thereto.** August Eckstein and Richard Pentney Eidsforth, 45, Chapel-street, Salford, Manchester.

JANUARY 18.

1180. **Improvements in solutions for use in primary batteries.** Hymen Levetus, Edward Moses Levetus, Walter Rowbotham, and Charles Levetus, 47, Vittoria-street, Birmingham.

1181. **Improvements in solutions for use in primary batteries.** Hymen Levetus, Edward Moses Levetus, Walter Rowbotham, and Charles Levetus, 47, Vittoria-street, Birmingham.

1202. **Improvements in telephonic apparatus.** William Edward Langdon, Midland Railway, Derby.

1206. **Apparatus for measuring and recording electrical currents.** John Friends and Thomas John Murday, 20, King-street, South Shields.

1234. **Method of varying the speed of multipolar electric motors.** John Augustus Essberger, 46, Lincoln's-inn-fields, London

1260. **Self-inductor current alternators.** Paul Boucherot, 60, Queen Victoria-street, London.

1262. **Improvements in electric arc lamps.** William James Davy, 40, Chancery-lane, London.

JANUARY 19.

1279. **An automatic resistance coil for the regulation of electric currents.** Samuel Sealy Allen, 52, Woodstock-road, Bedford Park, London.

1317. **Improvements relating to electric lamps.** Robert Hacking and George Brand, 78, Fleet-street, London.

1318. **Improvements in armatures for dynamo-electric machines.** Rookes Evelyn Bell Crompton, Sydney Linton Brunton, and Percy Privett, 55, Chancery-lane, London.

1353. **Improvements in the application of telephones to electric bell systems.** Frederick Hodgson and George Alfred Edwards, 8, Agincourt-road, Hampstead, London.

SPECIFICATIONS PUBLISHED.

1881.

4409. **Telegraph conductors, etc.** Callender. (Second edition.

1893.

25009. **Electric cigar lighters.** Schindler.

1894.

191. **Dynamos.** Keith.

192. **Electric drills, etc.** Keith.

4113. **Electric batteries.** Barnett.

4190. **Electrically illuminated signs, etc.** Berry and Harrison.

4540. **Overhead conductors of railways and tramways.** Siemens Bros. and Co. (Siemens and Halske.)

5340. **Electrical resistance coils.** Fleming.

5592. **Counterweights for electric light pendants, etc.** Grubb and Sturgf.

21098. **Obtaining electrical energy from fuel gases.** Borchers.

22821. **Conduits for electrical conductors.** Tatham.

NOTES.

Lecture.—A lecture on "Magnets and Electric Currents" has been delivered by Prof. J. A. Fleming at Peterborough.

Obituary.—The death has just occurred of Mr. T. Bird, manager of the works of the General Electrolytic Company, at Farnworth.

Ship-Lighting.—The "Majestic," which was to be floated yesterday at Portsmouth, is lighted electrically, and is equipped with search-lights.

Australia.—The inhabitants of Adelaide have been polled to decide whether the city should be lighted by gas or electricity. The result of the polling was in favour of gas.

Acton Tramways.—A report of an interview with Mr. J. Clifton Robinson, the promoter of the proposed Acton electric tramway, was published in *London* of the 24th ult.

Institution of Civil Engineers.—On Tuesday next, at 8 p.m., a paper will be read on "The Mechanical and Electrical Regulation of Steam-engines," by Mr. John Richardson, M.I.C.E., of Lincoln.

Transmission of Power in Italy.—A scheme for the utilisation of the hydraulic power of the Naviglio Grande, to the extent of 18,600 h.p., has been advanced by Messrs. G. B. Conti and L. Greppi

Telephony in Germany.—A telephone exchange with 32 subscribers has been opened at Landshut, Bavaria. It is connected with the long-distance telephone system of Bavaria on the right bank of the Rhine.

Telephony.—The National Telephone Company are developing their system in Kent. During the past week Tunbridge Wells and the intermediate towns of Tonbridge, Hadlow, Wateringbury, Yalding, and other places have been telephonically connected with Maidstone.

Royalty and Electric Traction.—An electric tramway is in course of construction at Nice, and is expected to be completed by March 1. This line will be used by her Majesty the Queen, who is expected to arrive at the Hotel Cimiez on the 15th of that month.

Society of Arts.—On Tuesday next, at 8 p.m., a paper by Mr. Gleeson White will be read on "Drawing for Process Reproduction." On Wednesday, at 8 p.m., a paper by Mr. Geoffrey Drage will be presented on "The Labour Question in the Colonies and Foreign Countries."

Students of the Institution.—A students' meeting of the Institution of Electrical Engineers will be held in the library of the Institution, 28, Victoria-street, on Friday next, 8th inst., at 8 p.m. A paper on the following subject will be read: "The Magnetic Condition of Matter" (with experiments), by Mr. Chas. E. S. Phillips.

Society of Engineers.—The first ordinary meeting of this society for this year will be held on Monday next at the Westminster Palace Hotel, commencing at 7.30. Sir Robert Rawlinson, K.C.B., hon. member, will present the premiums awarded for papers read during last year, and the president, Mr. W. G. Peirce, will deliver his inaugural address.

"Our London Letter."—The "London letter" of the *Indian Engineer* of January 5 contains a paragraph reproduced from our columns concerning an electric piano. It is a pity that the "writer" of the "London letter" does not know that it is "righter" to acknowledge an editorial comment than to cut it out from a contemporary and print it as his own.

Fire.—We regret to learn that a fire occurred on Wednesday at the Bournbrook depôt belonging to the electric car section of the Birmingham Central Tramways Company. The battery-room was burned down, and as a result the service of cars had to be suspended and omnibuses used instead. It is expected that the service will be resumed in a few days.

Gas Journals, Please Copy.—Will the gas journals which are so fond of decrying the electric light reprint the following: On Tuesday afternoon, while the gas-mains were being repaired in Gidling-street, Dockhead, Bermondsey, an explosion occurred. An elderly lady and a boy were injured, and considerable damage was done to the surrounding property.

Carbonne.—At this town, in the department Haute-Garonne, an electric lighting scheme has been carefully drawn up and approved. The total outlay will not exceed £3,000, which sum will be borrowed and repaid in 30 years by annuities of £160 each. Of these the communal funds take half, leaving the rest for private subscription. Water power is to be used

Railway Rates.—Members of the London Chamber of Commerce are reminded by the council of previous circulars recommending them to lodge complaints with the Board of Trade, not later than February 25, of any increases of railway rates within their own experience which are of such an unreasonable character as to justify resistance to the demands of the railway companies.

Merchandise Marks.—In view of the early opening of the new session of Parliament, and with the object of ascertaining the present drift of commercial opinion on the subject of the Merchandise Marks Acts and their operation, the council of the London Chamber of Commerce have decided to hold a conference of members in the council-room of the Chamber on Wednesday, March 6, at 2.30 p.m.

Dock-Lighting.—A new dry dock, said to be the largest in the United Kingdom, has been opened by the Wallsend Slipway and Engineering Company at Wallsend-on-Tyne. There is an installation of electric lamps to facilitate the carrying out of repairs at night, and to enable the firm to undertake the work of repairing and refitting vessels constructed for carrying oil in bulk.

Exhibition of Agricultural Machinery.—An international mart of agricultural machinery will be held in Vienna from 4th to 7th May next. Mr. F. Stockinger, (the Austro-Hungarian Consul-General), of 11, Queen Victoria-street, E.C., who will give further information on the subject, states that the exhibition will include electrical machinery such as would be used in forestry, sawmills, celluloid factories, etc.

Electric Light Tariff.—At Soissons, a French town in the Aisne department, a commission nominated by the Municipal Council decided at its last meeting to appoint two experts for examination of and report upon the tariff of charges drawn up for the proposed electric light supply. One expert will be appointed to deal with legal and administrative points, the other, an electrical engineer, is to advise on technical matters.

Dangers of Coal Gas.—According to the annual report of Captain Simonds, no less than 284 fires were caused last year in the Metropolis by what are termed gas explosions; but not a single conflagration has been traced to the use of the electric light. This fact will be a trifle of a "choker" for that gassy paper, the *Journal of Gas Lighting*, but one cannot expect the latter to have the candour to admit the truth of this statement.

State Telegraphy.—One of the *Daily Chronicle's* young men has endeavoured to interview Mr. W. H.

Digitized by Google

Preece on the subject of the twenty-fifth anniversary of the transfer of the telegraphic system to the State. As might have been expected, the fascination of the *Chron.* was not sufficient for Mr. Preece, and he therefore asked Mr. James Hookey to dispose of the young man. He did so, and the young man soon took his "hookey."

Cable Rates to South Africa.—It is stated that, contrary to general expectation, the negotiations between representatives of the South African Powers and the cable companies for the reduction of the cable rates between London and South Africa have resulted in a deadlock. Hitches have occurred, one of which is the refusal of President Kruger to agree to pay the amount of subsidy desired. The negotiations are therefore indefinitely postponed.

Yachting Exhibition.—A yachting exhibition was opened at the Royal Aquarium, Westminster, on Tuesday. Mechanically-propelled craft are numerous, and include launches driven by steam, oil, naphtha, and electricity, and Daimler motor-boats. Amongst other exhibitors in this section may be mentioned the British Aluminium Company, Westminster; Thames Electric Launch Company, Twickenham; Mr. S. S. Saunders, Goring; and the Liquid Fuel Engineering Company, East Cowes.

Battersea Polytechnic.—The Battersea Polytechnic, which was opened early last year, appears to have been educationally a great success. People are beginning to find out the advantages it has to offer for what are merely nominal payments, and it shows this year a general average increase throughout all the classes of about 35 per cent. In some classes the increase is but small, but in others, such as electrical engineering, there has been an advance of over 100 per cent. Science and technical classes have generally increased about 80 per cent.

International Telegraph Conference.—At the meeting of the international telegraph conference held in Paris in 1890, it was decided that an official vocabulary should be prepared by the International Telegraph Office at Berne, the employment of the vocabulary becoming obligatory for European, but not extra-European, telegrams in code, after the expiration of three years from the date of its publication. The volume has now been issued, and it will therefore come into obligatory use in January, 1898, for all code telegrams transmitted between European countries. The next meeting of the international telegraph conference will be held in 1896.

Bordeaux Exhibition.—The limit of time up to which applications for space may be lodged with the Société Philomathique de Bordeaux or the secretary of the London Chamber of Commerce has been extended to February 28. The exhibition opens in the beginning of next May and closes in the following November. The society are also particularly anxious to have a representative display from the British electrical industry. Firms which take an interest in this exhibition should put themselves in communication at once with the secretary of the London Chamber of Commerce, Botolph House, Eastcheap, E.C., or with the Société Philomathique de Bordeaux.

"Electric Power."—*Electric Power*, now in its seventh year, makes its bow to the public for January in an entirely new form and dress. It will henceforth appear as a magazine both as to size and character—a change which the readers of electrical science will greatly appreciate. The first number of the new form is handsomely printed, and contains many excellent illustrations. The reading matter is less technical in its nature, and is interesting to those who wish to know something of what is going on in electricity, and yet do not care to make a study of the science. Electricity is being applied so universally now that every progressive person should read *Electric Power*.

Electric Lighting in France.—The electric light will probably be introduced at Chamounix by next summer.—The Compagnie Urbaine have obtained a 27 years' concession for the electric lighting of Domfront, Orne.—An agreement has been come to between Mr. Honore Guiol, of Trans, and the Municipality of Draguignan for the erection by the former of a central electric light station in the town. The station will be installed at Trans, on the Arluby, an effluent of the Argeus, and will be worked by two turbines. There will also be a reserve in a steam-engine of at least 100 h.p.

Meter Prizes.—The Elihu Thomson electrical energy meter having obtained at the meter competition organised by the city of Paris a first prize of £200, Prof. Elihu Thomson devoted this sum to facilitate the study of certain theoretical questions of great interest, and a committee of French scientists was appointed to examine and report upon the dissertations sent in. The prize has just been awarded to an American scientist, Dr. A. Webster, but on account of another paper being of almost equal merit Prof. Elihu Thomson and others have contributed to offer an equal sum of £200 for the latter paper, the authors of which are Prof. Oliver Lodge, F.R.S, of Liverpool, and Mr. R. T. Glazebrook, F.R.S., of Cambridge.

Laying of New Mains.—The Westminster Electric Supply Corporation intend to lay mains and to construct street boxes in Clarges-street from Lambeth-mews to Curzon-street. The House-to-House Electric Light Company propose to lay mains in Redcliffe-square, and to place mains and construct street boxes in Cromwell-crescent. The Charing Cross and Strand Electricity Supply Corporation are about to lay mains and to construct street boxes in Buckingham-street and Duke-street. The County of London and Brush Provincial Electric Lighting Company having asked the County Council to accept four days notice instead of one month with reference to the laying of service lines from distributing mains already placed under ground, the Council have decided to accept such notice.

"Journal" of the Institution.—The current issue of the *Journal* of the Institution of Electrical Engineers contains the following papers: "Notes on Electric Tramways in the United States and Canada," by Mr. H. D. Wilkinson, member (supplementary paper); "Electric Traction, with Special Reference to the Installation of Elevated Conductors," by Mr. Robert W. Blackwell, foreign member, and Mr. Phillip Dawson, associate; and "Electrical Steep-Grade Traction in Europe," by Mr. C. S. du Riche Preller, Ph.D., member; and a full report of the discussion on all three papers. It also contains a communication from Mr. P. V. Luke, C.I.E. (director of the Construction Branch, Indian Government Telegraphs), descriptive of an interesting case of lightning on the telegraph line between Bombay and Bhusavat.

Jungfrau Railway.—One of the Swiss newspapers makes merry in a good-humoured way over the proposal to build a railway up the Jungfrau. "This is no question," it says, "of compressed air. Electricity will afford the means of traction. The tunnels will be lighted by it; there will be stopping places at all the principal glaciers, and two miles up will be seen the notice 'The Eiger Station—ten minutes to wait!' A natural glacier will be provided alongside the railway, and the train then passing round the huge mass of the Eiger will draw up at a plateau that is only clear of snow in the summer. Seven and a half miles at £40,000 a mile! That is what this project is to cost. Twenty years ago it would have been considered a chapter

Digitized by Google

out of one of Jules Verne's books. To-day the men of money who were afraid to give half-a-crown for one of Verne's books are willing to advance nearly half-a-million for the work."

Electricity in Metallurgical Operations.—The twenty-second annual dinner of the old students of the Royal School of Mines took place last week at the Criterion Restaurant, under the presidency of Mr. W. H. Greenwood. The chairman, in proposing the toast of "The Mining and Metallurgical Industries," reviewed the history of those industries during the past year. The toast was acknowledged by Prof. Roberts-Austen, who said that they were told that the age of steam was giving way to the age of electricity, and, as regarded the metallurgical industries, that was no doubt as true as it was in the case of other industries. He saw nothing to regret in that. The modern dynamo was the direct outcome of the work of Faraday, and Englishmen had taken a leading part in the construction of the great installation which was to make the Niagara Falls available as a source of power on the other side of the Atlantic.

Madrid.—It is stated in a recent issue of *El Correo*, one of the leading Madrid newspapers, that a meeting (very largely attended) of consumers on the circuits of the electric light supply company La Madrilene was held lately to appoint a deputation which should wait upon the manager of the company to lay before him the following demands: (1) payment of damages for the serious losses and inconvenience caused to so many by reason of the failure in supply for several days past; (2) promises of more constant supply in the future, coupled with a lower charge for meters; (3) a reduction of 10 per cent. on the tariff charges. The manager was at first naturally averse to falling in with these requirements, but after consulting with his board of directors in London *(sic!)* he was instructed to comply with all the demands thus made, with additional benefits as regards installation charges and cost of lamps.

Electricity in Mining Operations.—The Austrian papers are devoting space to descriptions of an installation for the electrical transmission of energy at the Tommen pits, near Fünfkirchen, Hungary. The Danube Steam Navigation Company own the pit, from which extraction had been suspended for some time. The *Colliery Guardian* states that when it became a question of exhausting the water which had accumulated and of starting coal-getting, it was decided, on economical grounds, to have recourse to electricity. For this purpose an engine, which was not used in the mine, was fitted up to drive a dynamo giving 80 amperes at 150 volts. The current was either transmitted to a motor placed at the bottom of the shaft at a distance of 227m., where the motor actuated a pump, or to a motor placed on the surface, 56m. distant, and capable of developing 12 h.p. The installation, which has not yet had any stoppages, was set to work on March 14, 1893.

"Dangers of Electric Currents."—Mr. Edward Evans-Lloyd wrote to the *Times* from Bordeaux on the 25th ult. as follows: "It is hardly necessary to insist on the dangers incident to electric currents, but having been a witness of the fatal results of a careless manipulation of the machinery in connection with the electric tramway here, I venture to send you a short account of what happened in Bordeaux yesterday afternoon. It seems that the telephone wires run overhead parallel with those of the tramway, and that during certain repairs to the former wires they broke, and in their fall became entangled with a horse which was drawing a carriage in one direction, and with another horse in a cart going in the opposite course. The result was that both horses were killed instantaneously, as well as four unfortunate dogs happening at the same moment to be in the street. The driver of the carriage received an alarming shock, and was for some minutes riveted to his seat, though after a time he recovered."

Chloride Storage Batteries.—In our last issue we were able to announce the termination of the dispute which had arisen in connection with the chloride storage battery, and now the company working this battery in this country have brought out an illustrated catalogue pointing out the various uses to which this type of cell can be put. We have so often referred to the chloride battery that it will now be unnecessary to refer to its great advantages for lighting and traction purposes. The battery, which is made by the Chloride Electrical Storage Syndicate, Limited, of 16, Victoria-street, S.W., is also supplied by the Electric Storage Battery Company, of Philadelphia, U.S., and by the Société Anonyme pour le Travail Electrique des Metaux in France. The chloride battery is suitable for private installations, central stations, and for traction work; in the latter case the cells are specially protected. All interested in these branches will find in the catalogue information which will be found of value.

Rating of Machinery.—At the forthcoming meeting of the Association of Chambers of Commerce, a resolution from Bradford will be moved on this subject. It is to the effect that having regard to the action of the Chorlton Union in assessing the whole of the machinery and tools of Sir Joseph Whitworth and Co., Limited, and seeing that there has hitherto been no generally recognised or uniform system pursued by the different rating authorities in the matter of rating of machinery, and that such absence of system has frequently caused injustice, and whereas the Rating of Machinery Bill introduced into the House of Commons proposes to establish a regular and uniform system of rating of machinery throughout England, it be resolved that her Majesty's Government be urged to afford facilities this session for the consideration and passing of the Rating of Machinery Bill, and that a copy of this resolution be forwarded to the President of the Local Government Board, and to the leader of the House of Commons.

Refuse Destructors.—A report of an interview with Mr. F. H. Medhurst, dealing with the employment of refuse destructors, was published in the *Pall Mall Gazette* on Saturday. Towards the close of the report Mr. Medhurst said: "It is probable that the next few years may bring improvements in incandescent lamps, but in respect of generating plant and the conductors for conveying the electricity we have reached something akin to finality. Let me, as my last word, make it clear that the idea of utilising this waste heat in this manner does not originate with me. Prof. George Forbes was the first engineer to seriously propose such a scheme, in reference to Edinburgh, but nothing practical was done. Mr. Manville, too, has worked hard in the same direction, and has prepared a refuse-destructor scheme in conjunction with an electric light installation on a large scale for Shoreditch Vestry; but I believe the further consideration of the question has been postponed for some months." The interviewer forgot to record the work accomplished by Mr. Jones at Ealing.

Lightning and Telegraph Posts.—A French contemporary chronicles some curious effects which lately occurred to a number of telegraph posts during a thunderstorm. They appear to have shared in a violent lightning discharge which split some of them from top to bottom, others had large splinters taken off, their tops knocked away, or bore the mark of a wavy discharge in spiral fashion round the stems. The conclusion arrived at is that just as prudence forbids one

Digitized by Google

to shelter under a tree in a thunderstorm, so also the neighbourhood of telegraph posts is to be avoided. To our minds it seems curious that better provision was not made to carry away the discharge: it is usual to fix a lightning-conductor on every post, and this may have been done in this case, though apparently to small purpose. The erratic nature of lightning discharges is, however, well known, and since mechanical reasons forbid ensuring safety by giving the timber posts sufficient self-induction (!) to send the discharge always to earth down the wire, probably things must remain as they are.

The Pacific Cable Question.—A telegram from Ottawa on Tuesday states that the preliminary negotiations in connection with the proposed Pacific cable have made great progress during the past few weeks. The Canadian Government recently asked the views of the Australian Governments on the question of State ownership, and at the same time forwarded a revised offer on the part of the lowest tenderer to construct the line, comprising greater speed and a transmitting capacity of either 15 or 18 words a minute. With this change the cost was found to be much less than the estimate furnished at the Inter-Colonial Conference last year. No objection was raised by the tenderer to construct and maintain a cable *vid* Fanning Island. The Foreign Relations Committee of the Senate at Washington considered on the 24th ult. the resolution in favour of permitting the landing in Hawaii of the Pacific cable from Canada, and decided to present an adverse report. The committee recently appointed reported to the Senate, on Tuesday, an amendment upon the Consular Diplomatic Bill for the fiscal year appropriating a further sum of half a million dollars in order that a cable to Hawaii may be laid.

Science Schools.—The Science and Art Department of the Committee of Council on Education have issued a circular containing a scheme of rules for organised science schools. These rules will take the place of Sections 22 to 28, pp. 33 to 36, of the Science and Art Directory, and will come into force after the next examination in May. The most important feature of the scheme is the introduction of payment on inspection instead of payment on results for by far the larger part of the instruction given in organised science schools. This modification, which applies to 120 science schools in the United Kingdom, has become possible only since the appointment of a staff of science and art inspectors. Provision is also made for a certain amount of literary instruction being given whilst the student is pursuing his science curriculum. Greater freedom is given to the teacher as to the syllabus he is to teach in the first two years of a student's course. A choice of advanced courses is given; an alternative programme suitable for women is formulated, and instruction in subjects specially adapted to them is demanded; and practical instruction must be given in the subjects of science simultaneously with the theoretical instruction.

Another Explosion.—An explosion occurred last week in front of the Guildhall at Rochester, followed by the lifting up of some of the stones of the street pavement." On Wednesday Major Cardew, R.E, inspector to the Board of Trade, made an inspection of the scene of the explosion in High-street in the presence of Mr. Hurrell, electrical engineer and managing director of the Chatham and Rochester Electric Light Company. The statement of Mr. Hurrell is to the effect that the explosion occurred at the electric light company's No. 7 sub-station, and about 20 paving stones round and near the iron cover had been displaced. The explosion, it is said, had resulted from an accident which might not occur again in a thousand years. A spark had been found playing on a brick, which had fallen, owing to its being displaced by frost, on the high-tension terminal and on the iron tube of the low-tension main. Mr. Hurrell attributed the explosion to a faulty gas-main, and the gas coming in contact with the electric current had exploded in the ground near to the vault. Major Cardew intimated that he would submit a report to the Board of Trade, who would decide whether his visit should be followed by an official enquiry.

Electrical Communication with Lighthouses.—The scheme recommended by the Royal Commission having been sanctioned by the Treasury, telegraphic and telephonic communication in connection with the Liverpool lifeboat service have been established by the Post Office authorities. The new system provides telephonic intercommunication between the lifeboat station at Formby, the coastguard station at Blundell Sands, the Prince's landing-stage, the ferry-stage at New Brighton, and the Liverpool head post office, besides telegraphic communication between the latter office and the "look-out" stations at Voelnant (Point of Air), Hilbre, Hoylake, Bidston, and the Crosby lighthouse. On the Welsh coast the lighthouses on the Great Orme's Head and at Menai are now placed in communication with the lifeboat stations at Llandudno and Penmon respectively. The lighthouse on the South Stack, the signal station on the North Stack, and the lifeboat stations at Rhosneigir and Rhoscolyn are in direct telephonic communication with the coastguard station at Holyhead. The work of providing telephonic intercommunication between the coastguard station at Amlwch and Cemmaes, the signal station at Point Lynas, and the lifeboat stations at Bull Bay and Moelfra (the scene of the wreck of the "Royal Charter") will be perfected before the end of February, as also a telephonic extension to the lifeboat station at Llanddwynn, Carnarvon Bay.

Metropolitan Provisional Orders.—The Highways Committee reported to the London County Council on Tuesday that five applications have been made to the Board of Trade for electric lighting provisional orders this session. Three of these are made by the County of London and Brush Provincial Electric Lighting Company for powers in Battersea, Newington, and St. Olave's respectively, and the local authority in each case objects to the granting of the order; while the Charing Cross and Strand Electricity Supply Corporation seeks by the Strand order to include in its area of supply the Strand district, and the Notting Hill Electric Lighting Company by the Notting Hill order seeks to include in its area a part of Kensington, with respect to which the provisions of the House-to-House Company's order of 1889 were revoked on that company's application in 1893. As it was necessary that any observations upon the orders should be made to the Board of Trade as soon as possible, the Highways Committee have submitted on behalf of the Council, for the Board's consideration, certain amendments of the four first-mentioned orders to bring them into accord with the electric light legislation of 1892, and they have under consideration the question of suggesting to the Board the expediency of provisions being inserted limiting, if not prohibiting, the adoption under any one of the orders of a system of supply which would involve the construction of transformer-chambers of large size under the public streets. The committee do not consider that any action should be taken in regard to the Notting Hill order.

New Swindon Junior Engineering Society.—The members of this society assembled in good numbers last Saturday at the Mechanics' Institution to hear a paper on "The Distribution of Electrical Energy," by Mr. Douglas T. Heap, A.I.C.E., M.I.M.E. Mr. Heap received his mechanical training in the G.W.R. works at Swindon, and has for some

Digitized by Google

years past held an important position under Messrs. Crompton and Co. He is an honorary member of the society, and travelled down from London to read his paper. The chairman, Mr. H. G. Cotsworth, pointed out that the only practical solution of the problem of the transmission of energy direct from the mouth of the coalpit to the manufacturing districts, there to be converted into mechanical work, was by the distribution of electrical energy, and suggested that the adoption of this system would play an important part in the abatement of the smoke nuisance. Mr. Heap opened his paper with an exhaustive analysis of the respective advantages, principles, and application of the two, three, and five wire systems of distribution. The great necessity of a simple yet efficient system of mains, and the conditions a good system should fulfil, were discussed at considerable length, and the Crompton, Kennedy, and Hopkinson bare-strip mains were described by means of diagrams. Most interesting information was imparted by a description of a piece, with joint, of the 10,000-volt Ferranti main as used between Deptford and London, kindly lent by the Institution of Electrical Engineers. As a sequel to the recent explosions of coal gas accumulated in culverts, the author thought that the next important step in electrical engineering should be the perfecting of the ventilation of main culverts. Cables, their requirements, and the relative advantages of pure rubber, jute, and paper as cable-insulating materials were considered; and in speaking of the insulation tests, Mr. Heap said it was imperative that the cable should be submerged in water at least 24 hours before testing. Porcelain insulators, he said, should be very closely grained (better obtained by deposition), and baked at 1,200deg. C. to give the best results. In conclusion, the author expressed his indebtedness to Messrs. Henley and the British Insulated Wire Company for samples of cables, and Messrs. Doulton and Co. for insulators and culverts. It was mentioned that Mr. J. W. D. Clinch will read a paper on "Hydraulic Cranes and Lifts" before the society on the 14th inst.

The "New Street Danger."—Under this title the *Lancet* makes some pertinent remarks bearing upon the subject discussed in this journal last and this week. Our contemporary says: "The 'new street danger' is losing its novelty. Owing to the alarm caused by the frequency and danger of such accidents, it is now proposed to present a petition to the Board of Trade that immediate steps be taken to prevent their recurrence. It is, however, difficult to believe that that Board, aware of the danger and fully informed of the facts, will delay effective action until urged forward under pressure of a public petition. It is not to be doubted—(1) that serious explosions may occur in connection with electrical leakage in underground mains both on the high-pressure and on the low-pressure systems; (2) that in consequence of leakage from high-pressure mains into the surrounding ground men have been injured and horses killed by electric shock; and (3) that such accidents are to be regarded as 'preventable.' The causes that lead to them are becoming fairly well known. It is recognised that among the measures to avert these occurrences are to be enumerated a due regard to the kind and construction of cables, care and foresight in the laying of mains, a proper 'earthing' of the outer conductor of concentric cables, efficient insulation, precautions to secure ventilation and drainage of culverts and junction-boxes, and an efficient inspection of the entire system. Such accidents are to be deplored, not only on account of danger to the public, but also in the interests of electric lighting. The electrical engineer is aware that long before he appeared on the scene with his cables and conduits and junction-boxes a notorious gas leakage had long held possession of the ground. It lies with him to meet the difficulty, and he will doubtless prove equal to the occasion. It has been suggested that some gas other than a mixture of coal gas and air—a gas 'distilled off the insulating substances' by the heated conductor—may at times be concerned in such explosions. This is possible, and in some cases perhaps probable. 'The man in the street,' however, is not seriously concerned to know the exact nature of the explosive gas, or the genesis of the spark or arc that ignites it, neither does he claim an opinion as to whether safety is to be found in gas-tight junction-boxes, or in a return to the old method of buried mains; but in self-defence he ventures to enquire whether new regulations are needed, whether existing ones are carried out, whether Rule 15, which provides that boxes shall be kept free from water and gas, be a reasonable one, and, if so, has it been duly enforced?"

The Government and Telephony.—A deputation from the Association of Municipal Corporations had an interview on Thursday of last week with Mr. Arnold Morley, with reference to the draft agreements entered into with the National Telephone Company and the New Telephone Company. The Postmaster General was accompanied by Mr. Spencer Walpole, Sir Robert Hunter, Mr. J. C. Lamb, Mr. Ogilvie, and Mr. Burrell. Sir Samuel Johnson, town clerk of Nottingham, introduced the deputation, who explained their objections to the agreement. The Postmaster-General, in reply, said the agreement was really one made by the late Government, the heads of agreement having been signed in July, 1892, by the then Postmaster-General, Sir James Fergusson; and all that he had done was to embody that arrangement into the formal legal document which was laid upon the table at the close of last session, and which would probably come up for discussion in the early part of the coming session. With the experience of the purchase of the telegraphs, the Government was not prepared to enter into the question of the compulsory purchase of the telephone system from the companies who had been created licensees of the Post Office. It must be remembered that they were not dealing with new licenses; the licenses were granted many years ago, and had still seventeen years to run, and it would be contrary to the public policy of this country to revoke those licenses until they expired by the effluxion of time. The Government, therefore, had no power to impose conditions on the National Telephone Company with regard to either maximum charges or equality of charge, without their full consent during the continuance of their license. The agreement would be of substantial advantage to the commerce of this country, because it would undoubtedly lead to a development of the trunk-wire system, and therefore to the granting of fresh facilities. He was surprised that the municipal corporations objected to their having the absolute power of settling the question according to their own needs; and if they reconsidered the question remembering that they had their formidable and powerful association at their back, he thought they would come to the conclusion that, after all, the decision which was arrived at in 1892 was a wise decision. Whether ultimately—and that he thought would at some time or other be the outcome—the State should take over the whole matter, in view of what took place in 1870 with the telegraphs, the Government were not prepared to consider the question of compulsory purchase; they had to make the best they could of the present position, and his belief was that when the agreement was put into operation it would prove to be a very considerable step in advance. He thought the municipal corporations would be acting unwisely if they were to give other than a friendly approval of proposals which had received the sanction of the House of Commons, both in the House itself and in committee.

THE INSTITUTION OF JUNIOR ENGINEERS.

TENTH ANNIVERSARY JOLLIFICATION.

When my editor handed me the invitation card and suggested that I might like to attend the dinner I shrugged my shoulders and said, "What, Saturday night again?" "Yes," he replied; "why not? Is not Saturday as good as any other day?"

I thought it was better—for one reason at least, but not for dinners. Still, I tried to get out of it. "Look here, chief, the card reads 'morning dress.' I can't go in morning dress; it's not proper." "Now, none of your hocus-pocus," he exclaimed, angrily; "just you get and go as you are, or rather—looking at my appearance at the time—as you were this morning."

I had to go. So I went as my chief directed. I knew it would be so. Half of the fellows were dressed, and the remainder were—in morning attire. This was rather vexatious, especially at the Westminster Palace Hotel.

Mr. Alexander Siemens, the president of the society, gave one and all a hearty welcome, reminding me of his gracious reception at the recent dinner of the Institution of Electrical Engineers.

I caught my eye on many familiar faces, one being that of the representative of my yellow-coated contemporary. I and he got chatting, and, as luck would have it, found that we were neighbours at the same table. The gentlemen present were:

LIST OF GUESTS.

Mr. Siemens (president).
Mr. Young (chairman).
Mr. Newman (vice-chairman).
Major-General Webber, C.B.
Prof. Ewing, F.R.S.
Mr. S. H. Wells.
Prof. Forbes, F.R.S.
Prof. Ayrton, F.R.S.
Prof. Hughes, F.R.S.
Mr. W. W. Beaumont.
Mr. Waldrom.
Mr. Vorley.
Mr. T. E. Gatehouse.
Mr. Spooner.
Mr. W. Powrie.
Mr. Boulding.
Mr. Tennant.
Mr. Fraser.
Mr. S. Cutler.
Mr. Dykes.
Mr. De Ritter.
Mr. W. Clarke.
Mr. Christ.
Mr. Le Tall.
Mr. Burtt.
Mr. Blakeney.
Mr. Fry.
Mr. Parker.
Mr. Walker.
Mr. Brown.
Mr. Winnoll.
Mr. Fuller.
Mr. Hosegood.
Mr. Fisher.
Mr. Arding.
Mr. L. Clarke.
Dr. Goldie.
Mr. Hunter.
Mr. Rea.
Mr. W. L. Powrie.
Mr. Youngman.
Mr. Woodhouse.
Mr. Beckton.
Mr. E. Cutler.
Mr. Sheppard.
Mr. Rowland.
Mr. Rugg.
Mr. MacAlister.
Mr. Morewood.
Mr. Pearson.
Mr. Crawter.
Mr. Narraway.
Mr. Cooke.
Mr. Wait.
Mr. Madden.
Mr. A. Willbond.
Mr. Wolff.
Mr. Rennie.
Mr. Taylor.
Mr. Kennett.
Mr. Morrison.
Mr. L. Gates.
Mr. E. Gates.
Mr. Roberts.
Mr. A. Marshall.
Mr. R. Marshall.
Mr. Jones.
Mr. P. Wells.
Mr. J. G. Sneath.
Mr. H. Johnson.
Mr. Leonardt.
Mr. J. N. Boot.
Mr. Gill.
Mr. Boot.
Mr. Marriott.
Mr. Newson.
Mr. Sneath.
Mr. Bignall.
Mr. Gatehouse.
Mr. Dunn (secretary).
Mr. Dickson.
Mr. Stanley.
Mr. King.
Mr. Lane.
Mr. Stuart.
Mr. Johnson.

If you want to enjoy yourself a year hence, I would advise you to go to the next dinner of the Institution of Junior Engineers. I don't want to tell any secrets, but I cannot refrain from saying something of the proceedings on the present occasion. It was essentially a jollification. Wit and satire abounded, and it only required the presence of Mr. R. E. Crompton, who I am sorry to say was absent, to complete this interesting gathering.

TRICKS OF THE STAGE.

I do not know whether it was part of the programme, but after asking the gentlemen on the right and then those on his left to drink with him, Mr. Siemens forgot the gentlemen in the centre. So we in the centre rose in a body and—sat down again.

The president, who mentioned the absence of Prof. Perry through illness in his family, and of Sir Arthur Rollit, M.P., caused some amusement by, in the same breath, saying, "Gentlemen, please charge your glasses."

The toast of "The Queen" was honoured, and the National Anthem sung. It is rather mysterious that the presence of electricians at functions of this kind should cause a displacement of property. I do not mean a disappearance thereof. At Tunbridge Wells, for instance, on the occasion of Sir David Salomons's banquet three weeks ago, the discordant blasts of two trumpeters caused a pile of plates to smash. At least, so the *Electrical Review* stated. My own impression, however, was that a highly-charged body close to the plates did the mischief.

Now, at the Westminster Palace Hotel on Saturday, when the electricians joined in the singing of the National Anthem, a table bell was seen to suddenly *walk* towards the edge of one of the tables and fall with a bang on the floor. I hope Maskelyne and Cooke's tricks are not going to form part of the proceedings on future occasions. If so, I shall ask my chief to send the "Human Magnet" to represent him, for I declare emphatically that I will not go; and when I say I won't—why the "Human Magnet" draws me.

The toast of the "Royal Family" having being duly honoured,

The president gave some useful advice. I wish I had met him years ago, because that counsel would have served me in good stead—at least it might. At all events, it had no effect upon the members of the Junior Engineering Society. What do you think Mr. Siemens said? "Gentlemen, I have a communication to make to you. Those who are accustomed to smoke—smoke; those who are not, don't try." Of course the result was the reverse of what the president had anticipated. Everybody *did* smoke, and in half an hour there was not a dry eye in the room. I wonder how those who then smoked for the first time felt after the dinner?

THE LION AND THE LAMB.

Mr. SIEMENS, in proposing "Her Majesty's Sea and Land Forces," paid a tribute to these two branches, and referred to the time so often spoken of when the lion "would lie down with the lamb—*outside each other.*" If they wished for peace, let them be prepared for war. As an instance of German military life, he amused those present by stating that many persons entering the service were ignorant, but that they thereby learned how to read and write—and to wash themselves. When once asked whether he thought it was a good thing for a young man to be taken from his friends for military service, he replied, one might say with Scotch caution, that "it depends upon the family." Another little story was that of a major who, in the Franco-German War, when the French were peppering the Germans from the opposite bank of the river, was so absorbed with a momentous question about the river that when plied with questions he remarked, "I think there are trout in it."

Major-General WEBBER, with whose name the toast was coupled, responded by referring to the connection between art and science and engineering. As if he had been somewhat ruffled by "Simple Susan," he stated that the admiral of the present day was not the frantic old rascal now being represented in "Rebellious Susan." He impressed upon them the fact that many in the army were engineers; that mighty generals in the past had been engineers; and that if it were not for their engineering knowledge, the army would not be half so efficient as it is.

Mr. WM. POWRIE proposed "British Commerce," which was responded to by Mr. SPOONER.

The president, in calling upon Mr. R. W. Newman (vice chairman) to give the toast of "The Engineering Professors," asked the latter not to be too hard upon the professor, who not long ago had had Mr. Newman under his thumb. Instinctively I knew something was about to happen, and I have not yet settled in my own mind whether the whole thing had not been pre-arranged.

Mr. Newman rose with a merry twinkle in his eyes. I have seen that sign before, and know what it means. It is an indication that a crossing of swords is about to take place. It did. But before he commenced I hastily picked

Digitized by Google

up the menu, or, as Mr. Siemens would put it, the *speisekarte*. There I saw at the top illustrations of a lobster and a crab engaged in mortal combat with swords. It was something like this:

LOBSTER—CRAB. THE INSTITUTION OF JUNIOR ENGINEERS.

I wonder what this means. Surely it is not a new definition of Ohm's law.

ENGINEERS' VIEWS OF PROFESSORS.

Mr. NEWMAN, in giving the toast, said that as junior engineers they had a kind of impression that the engineering professors were a kind of superfluity. (What! who was it cried out "Oh"?) They seemed to think that the only road to success was practical training. But those who knew the abuse of putting a young lad direct from school into a shop, were aware that it was a wrong step to take. It seemed to him that the future engineer should be placed, say, for two years under one of those gentlemen, the professors. (I made no mistake this time, for I distinctly heard "hear, hear.") The speaker regretted that he had not remained longer with Prof. Reynolds, of Manchester. When he complained to that gentleman that he would prefer the practical side of life, the professor replied, "I hope you will get it." He had always remembered those words. Now, however, he would like some of the practical diluted with a little of the theory. Twenty years ago—and everybody laughed at this sally—the professor was in his infancy; he was like a baby, and as he was getting older he was getting kicked about from pillar to post. As, however, years passed by, they would more and more feel that their future training should be laid on a scientific basis, and not upon the elementary education which they received at schools. (No, not Board schools, gentlemen of the daily Press, and a little less ——phemy please.) As an institution they had much to thank the professors for what they had done for them.

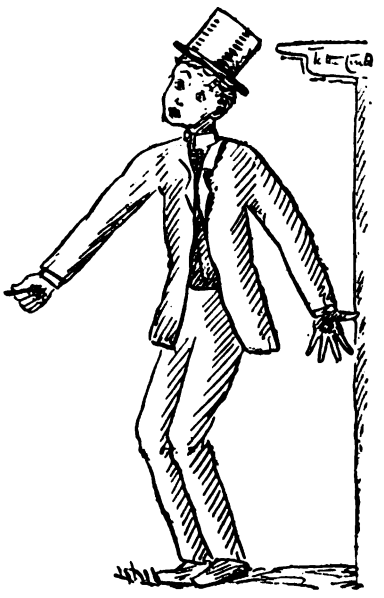
Prof. W. E. Ayrton acknowledged the toast. It did not require a glance at the toast list to inform me that he would do so. His diligent attention to the remarks made by Mr. Newman afforded sufficient proof, and when he rose I knew that he had a card up his sleeve. It was the trump card, and it won. It was well played, and no one could have played it better. When he got up from his seat, with his eyelids cast down and his hands upon his hips, he got the desired effect. A storm of applause burst through the room, and the professor, bowing his head like a weeping willow, knew that his hour of triumph had arrived.

THE TRUMP CARD WINS.

Prof. AYRTON, with the twinkle of mischief in his eyes, said that, of course, fun had been poked at professors. It was always so, and he supposed it was because there was a popular impression that teaching was the refuge of the destitute, so that when a man had convinced himself that he had no knowledge he straightway became a professor. A professor imparted his ignorance to his pupils. The subdivision of labour had, however, rendered it impossible for the master of the works to give to every individual apprentice that sort of paternal instruction which he formerly did, so it had been given to the technical teacher to help the master of the works. It was therefore not to be wondered at that the methods employed by the technical teacher were quite different from those adopted by the schoolmaster. There were three periods in the life of a man. They were (1) from birth to seven years, (2) from seven years to 17, and (3) from 17—until he died. During the first seven years the infant was guided by his own experience; during the period of 10 years he was guided by what his grandfather had done, and that was wrong; and during the latter portion of his life—well—— The professor then went on to say that since he had been in the room he had received a communication from a young girl (I fail to understand why there were so many "Oh's!" and laughs at this remark. Certainly it is in order for a professor to receive such a note. I am sure I should not have objected). Well, if a young girl was not satisfactory, he would say a young lady. He was her guardian. It was a letter with illustrations—a remarkable letter. Then the professor held up the letter, which he read, and showed the illustrations. I give below the lines, together with the pen-and-ink sketches. As a result, I am determined to become a professor at once.

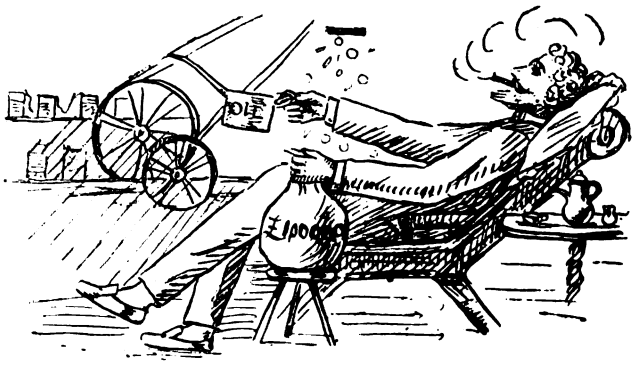
MISS M——'S VERSION OF "PUT A PENNY IN THE SLOT."

It is rumoured that Ayrton and Perry
A wonderful system have got
For the teaching of practical science
By putting a coin in the slot.



A student arrives at the Central,
His mind an absolute blank,
Yet he leaves simply teeming with knowledge
Imparted by turning a crank.

While as for my eminent guardian,
I suppose all his labour has been



To pick up the showers of money
And pensively oil the machine.

Digitized by Google

Then bring us the laurel and myrtle,
And bring us the garlands of bay,
Let us crown the brave Ayrton and Perry
For showing so royal a way.

Let everyone go to that college,
Let us all drop our coins in and see,
If her guardian would but turn the handle,
How wise even Tina might be.

A FIRST PROPOSAL.

In the one case you will see the perfect idiot going to the Central; in another he comes out with a diploma after one day's course; in the third the professor is depicted lying on a sofa, picking up money and oiling the machine; and in the fourth the professors are making merry over their success. I am perfectly certain that had I libelled the professors in the same manner as Miss M—— has done, I should get six months—holiday.

At any rate, my chief is so pleased with the artistic talent indicated by the sketches, that he is prepared to enter into an arrangement with Miss M—— to regularly contribute to this journal. Consequently, if Miss M—— will call at this office, I shall be happy to make arrangements, on behalf of my chief, for Miss M—— to make sketches whilst I scribble, as in the case of the *Daily Graphic*. I wish it to be distinctly understood that no other application will be entertained.

Prof. EWING, who also acknowledged the toast, referred to the term "hysteresis" proposed by him years ago. At the time the investigations into the magnetisation of iron were made, no one had any idea that it would have such an important effect upon the industry. Even if the professor worked on the penny-in-the-slot system, he did not get his penny if he did not work the machine properly.

ORANGE V. BLUE.

Prof. GEORGE FORBES, who rose to propose what the president called the toast of the evening, "The Institution of Junior Engineers," has evidently been reading no electrical journal other than the *Electrical Engineer*. He mistook some uncomplimentary remarks published recently in my orange-covered contemporary anent professors as having emanated from my esteemed friend the *Electrical Review*. When he looked at Mr. Alabaster the professor said that he was convinced that it was not he, but Mr. Gatehouse, who was responsible for the statements referred to. When, however, he glanced at Mr. Gatehouse, he was quite sure that the latter was free from blame, and that it was due to Mr. Alabaster. But the professor here discovered that he was on the wrong track, admitted it, and blue won again.

I do not like No. 13. Neither does Prof. Forbes. He said that when he came into the room and found No. 13 was the number of his seat, something was going to happen. It did, and resulted, as shown, in the professor confounding orange colour with blue. The speaker then eulogised the importance of the institution, and, in praising their policy of visiting different works and thereby gaining an insight into various branches of engineering, referred to the projected excursion of the institution this year to Belgium.

Mr. H. Y. YOUNG (chairman of the institution) suitably responded.

Other toasts included "Absent Members," proposed by Mr. A. H. DYKES and acknowledged by Mr. H. S. WELLS; "The President," by Mr. W. W. BEAUMONT and responded to by Mr. SIEMENS; and "Mr. J. W. Dunn," the secretary, put by Prof. AYRTON, and suitably acknowledged by the SECRETARY.

MUSICAL HONOURS.

During the evening pianoforte solos were rendered by Mr. A. H. Stanley and violin solos by Mr. T. E. Gatehouse, whilst recitations were given by Messrs. A. W. Marshall and W. T. Dunn.

At 11.25 I hastened away to catch my train, whilst those remaining stood up to warble "Auld Lang Syne." Ever since then the penny-in-the-slot machine has been running through my mind, and if I can only manage to remain awake for two nights longer I believe I shall have solved the mystery of, if not perpetual motion or the hansom cab, certainly that of making money by becoming a professor. At all events, I can already see engraved on my door plate the words PROF. PRIVATDOCENT.

THE PREVENTION OF EXPLOSIONS IN CONNECTION WITH UNDERGROUND MAINS.

In our last issue we printed the opinions of some central-station engineers on this important subject, and we now give a further instalment.

Aberdare.

Messrs. GEO. WILSON AND CO. write that as their installation is an overhead one, they have no replies to give.

Brighton.

Mr. ARTHUR WRIGHT, the Corporation electrical engineer, reports that no culverts or conduits are used.

Chelsea.

Mr. PERCY STILL, the engineer to the Chelsea Electricity Supply Company, replies to the questions in the negative.

Dublin.

Mr. MARK RUDDLE, the superintending engineer, observes that he has experienced no trouble through accumulations of gas. Respecting ventilation, he states that ventilation through the joints of the street-box covers, assisted by the connections to arc lamp-posts, seems to be sufficient. In high-pressure systems there is less need of ventilation if there are no exposed connections. Still, conduits should be kept free from chance of gas accumulating. In low-pressure work, ventilation assisted by a current of dry air from a fan is most essential for many reasons. Where required, the culverts are trapped into the sewers. There has been no trouble on the point of electrolysis.

Dundee.

Mr. W. H. BROWNLEE, the engineer to the Dundee station, has not found any difficulty in regard to gas. The culvert is ventilated into the station chimney stack, and this method has proved successful. Mr. Brownlee regards as the most practical method of preventing explosions the provision of plenty of inlets for air, with a fan exhausting at the end of the culvert. The culverts are drained into the sewers at the lowest points through Buchan traps. There has been no trouble through electrolysis.

Exeter.

Mr. H. D. MUNRO, engineer-in-charge of the Exeter Electric Light Company, informs us that the company have had no trouble on the score of explosions. They have no conduits or pipes, the whole of mains, high and low pressure, being concentric lead covered and armoured, and there is a continuous metallic sheathing connected to earth over the whole system, including joint-boxes, switch-boxes, etc. This system, he states, should secure them from any risk of explosions. Mr. Munro considers that some system of forced draught would be the most practical method of preventing explosions in conduit systems. Sealed pipes and

Digitized by Google

ventilating shafts for boxes and chambers should be used in the case of pipe systems. In regard to drainage, the street boxes are drained to the sewers. Electrolysis has not caused any trouble.

Kelvinside.

Mr. W. ELSDON-DEW, resident engineer of the Kelvinside Electricity Company, states that no difficulty has arisen from accumulations of gas. The system adopted by the company is steel-armoured and lead-covered cable laid direct in the ground. He considers that this method will be used much more universally when its many advantages are recognised and the means of manufacture improved. Concerning drainage, the writer says that all the joint-box chambers are drained by means of a trapped drain connected to the main sewers.

Keswick.

Mr. JOHN SHIPP, the manager of the Keswick Company, states that in the past they have had considerable trouble through explosions of gas in conduits and pipes. Where the lines of cables run parallel or near to gas-pipes, the conduits and pipes are freed from gas by means of 1⅛in. iron pipes connected either to the manholes or to the culverts containing the cables, and fixed to the nearest building. This method has proved effective. No system of ventilation other than that mentioned has been tried. Mr. Shipp considers the most practical method of preventing explosions in conduits is by arranging for the escape of gas by means of pipes similar to those referred to. In pipe systems he would connect an outlet pipe to all manholes. Wherever practicable, all culverts have been connected to the main drain or sewer. No trouble has arisen through electrolysis.

Morecambe.

Mr. J. JOWETT, the secretary of the Morecambe Electric Light and Power Company, replies in the negative to all our questions.

Newcastle.

Mr. W. SHORT, the secretary of the Newcastle-upon-Tyne Electric Supply Company, writes that the company have received our letter of queries regarding gas explosions, but that they are unable to give us the desired information.

Northampton.

Mr. W. E. HEENAN, the engineer to the Northampton Company, has not experienced any difficulty in regard to accumulations of gas. The company have not adopted any method of ventilation. Dealing with the question of drainage, Mr. Heenan remarks that they have placed at the bottom of most inclines a drain with a syphon before entering the main drain. No trouble has been caused by electrolysis.

Weybridge.

Mr. H. C. BUCHANAN, the secretary of the Weybridge Electric Supply Company, writes that as all their mains are overhead he cannot give us any information on the subject.

We give below the opinions of other engineers:

Mr. E. Manville

has experienced trouble through coal gas on one occasion. It was due to gas accumulating in an arc lamp service pipe, and being fired by a faulty arcing switch. The difficulty has been overcome by plugging the entrances to the service pipes. Mr. Manville does not consider that ventilation is required, the conductors in all cases being insulated, and so not able to spark, and in contact with metal pipes the system concentric with the "outer" earthed. The most practical method of preventing explosions is to use concentric systems with the outer earthed. With regard to drainage, the pipes drain into drawing-in boxes with open bottoms. No difficulty has been experienced through electrolysis.

Mr. Francis H. Medhurst

has not experienced any trouble through the collection of gas in underground systems. Discussing the question of ventilation, he observes that he has employed a blower to force *dry* air through the whole system of pipes. This not only keeps insulation dry and good, but also forces out gas should any find its way into the pipes. The most practical method of preventing explosions in conduit systems is to adopt ventilation and frequent inspection, although he strongly disapproves of conduit systems. Concerning drainage, Mr. Medhurst states that he employs a drain in connection with the main sewer at the sub-station. In practice, no draining is necessary if pipes be all well jointed with yarn and lead and rubber washers used for junction-box covers and for bolting pipes to junction-boxes. He has not found any difficulty in regard to electrolysis.

Sir David Salomons.

In reply to our questions, Sir David Salomons cites the case of the City of London Company. The system used by the company comprises mains drawn into Callender-Webber casings for a small portion, but for the greater area of the city they are drawn into wrought-iron screwed tubes. Some cables are single, some concentric, some triple concentric—all kinds of makes. So far as regards risk of explosion in the tubes themselves, Sir David is confident that no danger whatever can arise in this portion of the system. Some years ago he experimented with iron tubing similar in character to that which is used in the City, and he was unable to burst the pipes by using coal gas and air in the most favourable proportions for producing an explosion—*i.e.*, about one part gas to seven parts air. In the case of the tubes in the City, the space being so largely occupied by the cable, the risk of the pipes bursting is practically nil. The Callender-Webber casing, he states, is perhaps not so favourable in this respect, although he does not think that any explosion of gas in these conduits would move the ground above. The service-boxes are small, and almost completely occupied with material, so that the risk of damage by explosion at these points is also exceedingly small. The really dangerous part of the system is the draw-boxes, which are very large spaces. The company have already had a few accidents at these points, the most recent one being that in Cannon-street. It was shown in this case that the danger of ignited gas and air in the tubes is nil. The gas was fired along the tube with no ill effects until it reached the draw-box. Sir David Salomons has always held that it is practically impossible to keep the gas out of the electric lighting system when laid in conduits, which must necessarily entail draw-boxes. He considers that ventilation will make matters worse, since it will tend to draw the gas from any leaky point in the gas-mains into the system more freely. Compressed air would undoubtedly cure the evil, but this is quite impracticable in a large network. There is only one way, to his mind, by which the evil can be remedied, and that is by leaving no space for the gas to occupy, or a space so small that if an explosion did occur no damage would result. Sir David long ago proposed filling all the large spaces, such as the draw-boxes, with sand or slag-wool. In both cases there are certain disadvantages attaching to this course. He has now hit on a plan which will remove the disadvantages, and it is going to be adopted as an experiment on parts of the City Company's system. It is that of putting the sand into sacks to occupy the larger space at the bottom of these draw-boxes, and to fill up the remainder of the space with smaller bags containing the same material. It will then, of course, be easy at any time under this arrangement to remove the sand if it becomes necessary to enter the box for any purpose.

Mr. James N. Shoolbred

has never had (nor heard of) any trouble at any of the town supply installations which he has laid down, such as Bradford and Brighton, arising from accumulations of gas or water, for the simple reason that he never makes use of conduits or pipes if they can be avoided. The cables are invariably of the underground "armoured" class, laid direct in a trench in the ground, which is filled in again. The interior of the cast-iron street boxes and other connections are filled up solid, and so kept air and water tight. The filling can readily be removed should the electric connections be required to be exposed for testing or other purposes. The brick pits in which street boxes are placed (if required to be readily accessible), as well as the protecting brick conduits (at road crossings, etc.) and the iron protecting pipes, are allowed facilities for drainage into the adjoining soil, etc. Furthermore, interruptions in the

Digitized by Google

electrical supply and extinctions in the lighting have been prevented (at the above towns) by a suitable reserve of electrical storage; whilst electric shocks fatal to life have also been avoided by adhering to low pressure in the mains as defined by the Board of Trade regulations. Mr. Shoolbred states that the numerous accidents set down to electricity which have occurred of late, have disclosed in the several enquiries which have followed them a large amount of carelessness, and of disregard for the proper safety of the public, both in the design and in the working of the respective electric installations. He hopes, therefore, that a careful consideration of the above-stated precautions may not be thought ill-timed or out of place at present, when so many new electric installations are being laid down, the more especially, since the above two electricity supplies, as well as others, both in the Metropolis and in the provinces (and where similar precautions are in use), have been preserved entirely during the past few years from any of the so-called accidents due to electricity.

ELECTRIC DISCHARGE THROUGH GASES.*

BY PROF. J. J. THOMSON, M.A., SC.D., F.R.S.

One of the most important and interesting branches of physical science is that which deals with the connection between electrical and chemical effects. The investigations on electrolysis made within these walls by Davy and Faraday proved that the important class of electrical phenomena associated with the passage of electricity through liquids, are connected in the closest way with chemical action. They proved that no electricity will pass through most liquids unless chemical action occurs, and that for each unit of electricity which passes through the liquid there is a definite amount of chemical decomposition. This case, though it is one where the laws are most accurately known, is but one among many electrical phenomena which are inseparable from chemical action. So many instances of this kind have been discovered that we may perhaps venture to hope that we are not far from the time when it will be universally recognised that many of the most fundamental questions in chemistry and electricity are but different aspects of one and the same phenomenon. Anything which throws light on the connection between electricity and matter, interesting as it is on its own account, acquires additional interest when regarded as elucidating the connection between chemical and electrical effects, and no phenomena seem more suitable for this purpose than those which are the subject of the discourse this evening—the discharge of electricity through gases. For in gases we have matter in the state in which its properties have been most carefully studied, while the investigation of the electrical effects is facilitated by the visibility of the discharge, affording us ocular, and not merely circumstantial, evidence of what is taking place.

The points to which I wish to refer particularly this evening are—firstly, some phenomena connected with the passage of electricity from the gas to the electrode, or from the electrode to the gas; and secondly, some of the properties of the discharge when its course lies entirely in the gas. By taking a long discharge tube, say, one 50ft. long, and observing the luminous discharge through a rotating mirror, we can trace the course of the luminosity due to a single discharge, say, one due to once breaking the primary circuit of an induction coil; if we do so we find that the luminosity follows the direction of the positive current through the tube. That is, the luminosity begins at the positive electrode, it then rushes down the tube with enormous velocity, but when it gets to the negative electrode it receives a check; it does not disappear at once in that electrode like a rabbit going down a hole, but lingers around the electrode some time before entering it. In consequence of this delay in the positive discharge in getting out of the gas, there is an accumulation of positive electricity in the neighbourhood of the negative electrode until the potential fall at this electrode increases to about 200 or 300 volts. The positive electricity which accompanies the discharge thus finds considerable difficulty in getting from the gas to the metal, though, as I hope to show you later on, as long as it keeps in the gas it meets with what we may, in consideration of the views sometimes enunciated on this subject, call a ridiculously small amount of resistance; its real difficulty is to get out of the gas. Though this effect has long been known, it is so important that I will venture to show one or two experiments which illustrate it. The arrangement of the first experiment is shown on the screen. The apparatus consists of a main discharge tube, across which is fastened a diaphragm made of excessively thin platinum leaf. There is a side passage from the tube, leading from one side of the diaphragm to the other; this is connected to a barometer tube, and by raising the cistern containing the mercury I can stop up the passage by a pellet of mercury. We will first observe the discharge when the side passage is open.

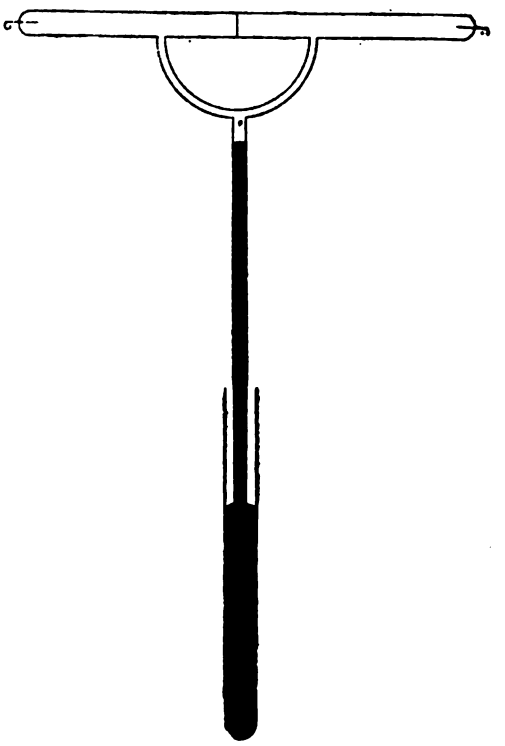


FIG. 1.

You see that the discharge, instead of passing across the thin piece of platinum leaf, takes the very much longer route round the side tube, so as to avoid crossing the metal. We will now raise the mercury-cistern and close the side tube by a pellet of mercury; the discharge now has no alternative but to cross the metal at some part of its course, and you see that the main portion of the discharge goes back into the main tube.

In the second experiment the metal diaphragm is replaced by a very thin plate of mica; when the side passage is opened the discharge goes round, but when this is closed by a pellet of mercury the discharge prefers to go across the mica than through the mercury. A second experiment which shows the same thing is the following:

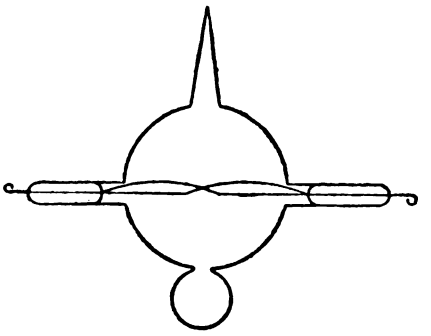

FIG. 2.

Two long electrodes are fused into a bulb, so that the tip of an electrode is a considerable distance from the place where it passes through the glass. We will now send an

* Paper read before the Royal Institution of Great Britain.

Digitized by Google

alternating discharge through the tube, and you will see, I think, that the discharge, instead of going straight across the short distance between the ends of the electrodes, goes from the tip of one electrode to the place where the other passes through the glass, thus staying as long as possible in the gas before passing into the metal. The appearance of the discharge shows that the positive electrode is at the end of the wire, the negative at the junction of the wire with the glass. Another interesting example of the difficulty the discharge experiences in passing from gas to metal is the discovery made by Profs. Liveing and Dewar, that when the discharge passes through a gas containing a large quantity of metallic dust, the light from the discharge, when examined in the spectroscope, does not show any of the lines of the metal.

The difficulty which the positive electricity finds in passing from the gas to the electrode depends a great deal upon the nature of the gas as well as upon that of the electrode; it is influenced by the position of the gas and the electrode relatively to one another in the electro-chemical series. I have lately made a series of experiments on this point in the following way: An alternating discharge from a high-tension transformer was made to pass between two electrodes fused into a bulb, which could be filled with the gases under examination. Another electrode connected to an electrometer passed into the bulb, and was arranged so that it could be moved about from one part of it to the other. When the electrodes were metal and the bulb was filled with the electro-negative gas oxygen, the electrode received a positive charge in whatever part of the bulb it was situated; if now the bulb was filled with hydrogen at atmospheric pressure, then in the regions remote from the arc the electrode received a positive charge, but in the immediate neighbourhood of the arc itself it received a negative charge. When the pressure was reduced the region in which the charge was negative contracted, and, finally, at pressures about one-third of an atmosphere seemed to disappear, and the electrode got a slight positive charge in whatever position it was placed. If now, instead of using metallic electrodes, we use well oxidised copper ones, and repeat the experiment in hydrogen, working at a pressure when there was only positive electricity when the electrodes were bright and polished, we find that with the oxidised electrodes every particle of positive electricity is taken out of the tube, and a negative charge is left. This negative charge remains until the copper oxide is completely reduced; when this occurs the negative charge disappears, and is replaced by positive. Thus, under the same conditions as to the nature of the gas and the pressure, the bright copper electrodes leave a positive charge in the gas, while the oxidised ones leave a negative charge.

The most probable explanation of these results seems to me to be the view that the communication of electricity from gas to the electrode, or from the electrode to gas, is facilitated by the temporary formation of something of the nature of a chemical compound between the gas and the metal. In all such compounds the metal is the electro-positive element, and has the positive charge, the gas being the electro-negative and carrying the negative charge. Now, consider the case when the negative charge is on the gas and the positive charge on the metal; then the gas and metal have got the charges proper to them in any compound they may form, and are thus in a fit state to combine, or, according to this view, allow the negative electricity to pass from the gas to the copper. But, now, suppose the gas was positively electrified, the gas and the metal have now opposite charges to those proper to them in a compound, and before the union of gas and metal in this state could result in anything but a most unstable compound, an additional process must be gone through—*i.e.*, the charges on the gas and metal must be interchanged. Thus the conditions for the combination of the gas and metal are more complex when the gas is positively electrified than when it is negatively electrified, and thus, on the view that the communication of electricity between the gas and the metal involves a sort of chemical combination, we see that the negative electricity will escape more easily from the gas to the metal than the positive. Now consider the case when the gas was hydrogen, the electrodes oxidised copper; the hydrogen combines now, not with the metal, but with the oxygen, forming water, in which hydrogen is the electro-positive element; thus, in this case, it is the positively-charged hydrogen which is in the state best fitted for pairing. The consequence is the positive charge would be most readily removed from the gas and the negative left, exactly the opposite to that which occurred when the electrodes were bright. This reversal, as I stated before, is verified by experiment.

I have hitherto only spoken of the phenomena which accompany the passage of electricity from the electrode to the gas, or from the gas to the electrode. I shall now pass on to consider the properties of the discharge when it is entirely confined to the gas. We may produce a discharge which, during the whole of its course, shall be confined to the gas in the way represented in the diagram. The two poles of a Wimshurst machine are connected to the insides of two jars, A and B, while the outsides of these jars are connected together by a metal wire wound so as to form a coil. The electricity from the Wimshurst machine charges up the jars, the difference of potential between the poles increases until a spark passes. The passage of the spark puts the insides of the two jars in connection, and the jars are discharged. The discharge of the jar, as was proved from the theory of electromagnet action by Lord Kelvin more than 40 years ago, and shortly afterwards confirmed by the experiments of Feddersen, is an oscillatory one, producing currents surging backwards and forwards through the wires with extraordinary rapidity.

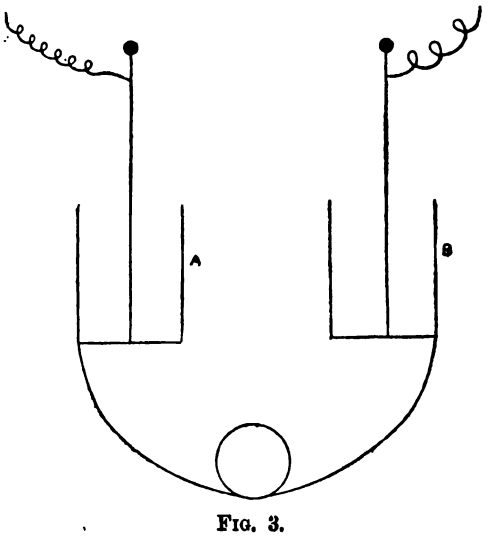

FIG. 3.

The subject of these oscillatory currents is one which in this year is tinged with melancholy. The year had hardly commenced when we lost Hertz, whose splendid work on these electrical oscillations is known to you all. The managers of this institution have marked their sense of the importance of this work by devoting a special lecture this session to this work alone, and they have entrusted that lecture to a most distinguished worker in the same field as Hertz. It would therefore be presumptuous on my part to refer in any detail to Hertz's work, but no physicist, and least of all one who is a member of Maxwell's university, could pass over in silence the death of Hertz. When Hertz began his magnificent experiments on electric oscillations, there were many theories of electrical action. When he had finished them there was only one—Clerk Maxwell's. Hertz's work was done with very much quicker vibrations than those produced by the apparatus now on the screen; this, however, gives rise to currents through the coil changing their direction some million times a second. If we place in the coil an exhausted bulb, the bulb in reality will be the secondary of an induction coil, and will be exposed to E.M.F.'s tending to produce circular currents parallel to the plane of the coil. I will now place a bulb inside this coil, and you see that a circular ring discharge passes through it, and this discharge passes entirely in the gas. The gas in the bulb now in the coil is the vapour of silicon tetrachloride; it happens to be the bulb which gives a brighter ring than

Digitized by Google

any others I possess. If this ring discharge passes through air at different pressures, the colour of the discharge changes very considerably. The first bulb I put in was at fairly high pressure, about one-tenth of a millimetre or so. I will now put in another at a lower pressure, and then one at a still lower pressure. Mr. Newall, who has been working at the spectra of these discharges, finds that at the pressure in the first bulb the spectrum is due to nitrogen; at the second stage it is due to mercury vapour; the bulb was pumped by a mercury-pump, so that there is in the bulb a certain quantity of mercury vapour. The apple-green colour in the more highly-exhausted bulb is due to some compound of sulphur, which has got into the bulb from the sulphuric acid used to dry the gas. Mr. Newall finds that if the ordinary discharge from a coil between electrodes is taken in such a bulb, there is no trace of this sulphur spectrum. He has also found that when the bulb is at a pressure intermediate between what I may call the mercury and the sulphur stage, when the mercury and sulphur lines are both visible, these sets of lines come from different layers, the sulphur lines coming from a layer nearer the surface than the other. If we take the discharge through a bulb containing oxygen, you see that the ring discharge is succeeded by a bright glow; at first the colour is somewhat opaque, but gradually sets more transparent and changes colour. This gives a continuous spectrum crossed by a few bright lines. If we take the discharge through cyanogen you see that the glow is even more persistent than the oxygen, though it is not so bright; all the gases which show this glow belong to the class of substances which polymerise—that is, whose molecules can combine with each other. I imagine that what takes place in bulbs filled with these substances is that the discharge produces a polymeric modification, and that this gradually returns to its original state, and while doing so gives out a phosphorescent light. It is in accordance with this that at a high temperature where ozone cannot exist a discharge through an oxygen bulb does not show any glow.

I said at the beginning of this discourse that gases were exceedingly good conductors of electricity. I will now endeavour to show an experiment which proves that statement. The apparatus which I shall use for this purpose is a slight modification of the one I have used

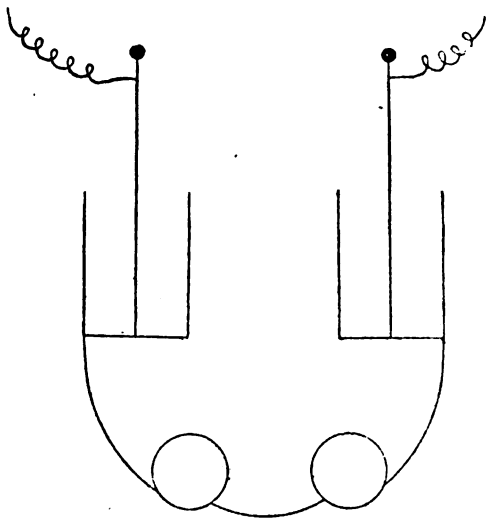

Fig. 4.

for producing the ring discharge—the only difference is that in the wire connecting the two coatings of the jars there are two loops instead of one. In one of these loops an exhausted bulb is placed to serve as a kind of galvanometer; the brightness of the discharge is an indication of the strength of the current flowing round the coil. If I place a second conductor in the other loop, currents will be started in it and part of the energy of the discharge will be absorbed; this will leave less energy available for the bulb in the first, so that the discharge in this bulb will be dimmer. The effect produced on the discharge will depend upon the conductivity of the substance placed in the second loop. The effect is not directly proportional to the conductivity; in fact, a perfect conductor would not produce any diminution, nor would an absolute non-conductor. For a given period and with apparatus of given dimensions, there is a certain conductivity which gives a maximum effect; this follows easily from the theory of induction of currents, but at this late period in the evening I will take a shorter course and prove it by an experiment. I put a piece of brass in this loop, and you see it produces but a small effect upon the brightness of the discharge. Instead of brass, I now insert a plumbago crucible, which, though a conductor, is not nearly so good a one as the brass, and you see the discharge in the indicating bulb is completely stopped. I will now place in the second loop an exhausted bulb; you see it produces a decided diminution in the intensity of the discharge in the galvanometer bulb. I now replace the bulb by another of the same size containing dilute sulphuric acid; you see it does not produce nearly so large an effect as the exhausted bulb; this might be due, as we have seen, to the sulphuric acid being either too good or too bad a conductor. I can show that it is the latter by putting a bulb in filled with a stronger solution, which has a higher conductivity than the weak solution. If the smallness of the effect produced by the weak acid were due to its being a better conductor than the gas, then increasing the conductivity would still further diminish the effect of the acid; you see, on the contrary, that the strong acid produces a distinctly greater effect than the weak, hence the rarefied gas in the bulb is a better conductor even than the strong electrolyte. Let us consider for a moment the molecular conductivities of the two substances, the rarefied gas and the electrolyte. The pressure of the gas is about one-hundredth of a millimetre, while in the electrolyte there are sufficient molecules of the acid to produce, if they were in the gaseous state, a pressure of more than 100 atmospheres. Thus the conductivity of the gas estimated per molecule is about ten million times that of the acid; this is greater than the molecular conductivity of even the best conducting metals. If the pressure of the gas is diminished below a certain point, the conductivity begins to diminish. I have here an experiment which I hope will show this. The apparatus (Fig. 5) consists of two bulbs, one outside the other; the inner bulb contains air at a low pressure, while the space between the two bulbs is a very high vacuum containing practically nothing but a little mercury and its vapour. The amount of mercury vapour in this space is, at the temperature of the room, exceedingly small, but as the

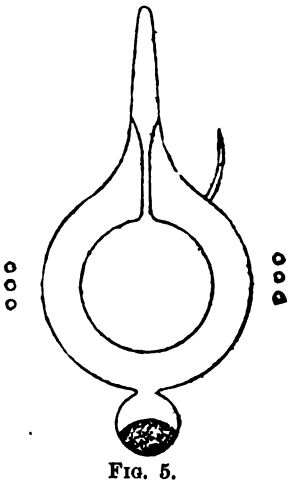

Fig. 5.

apparatus is heated the vapour pressure increases, and we are thus able to produce a fairly wide range of pressure in the space between the bulbs. The outer sphere is surrounded by the coil connecting the outer coatings of the two Leyden jars. When the space between the bulbs is a conductor, the alternating currents circulating in the coil will induce in this conductor currents whose inductive effect is opposite to that of the currents in the coil, and in this case this layer will screen off from the inner bulb the E.M.F. due to the alternating currents in the coil. If, on the other hand, the space between the bulbs is a non-conductor, the inner bulb will be exposed to the full effect of these forces. We now try the experiment: you observe

Digitized by Google

that when the mercury is cold, and consequently the pressure in the space between the bulbs very low, a bright discharge passes through the inner bulb, while the space between the bulbs remains quite dark; when we heat the mercury so as to increase the pressure of its vapour, a bright discharge passes through the outer layer, while the inner bulb is quite dark. The outer layer is now a conductor, and by its action screens off from the inner bulb the induction of the coil.

The last experiment I have to show is one on the effect produced by a magnetic field on the discharge. When the discharge has to flow across the lines of magnetic force, the pressure of the magnetic field retards the discharge; when, however, the discharge flows along the lines of magnetic force, the discharge is helped by the magnetic field. This is shown in the following experiment: A is a bulb, B a

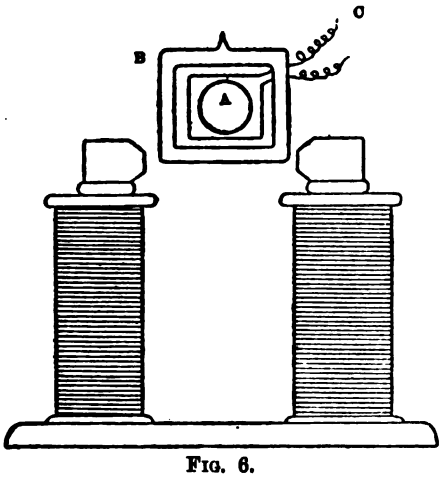

FIG. 6.

square tube (one side of which is placed between the poles of an electromagnet), the coil, C, which connects the outside coatings of the jars, can be adjusted so that when the magnet is "off" the discharge passes through the bulb, but not round the square tube; when, however, the magnet is "on," the discharge passes in the square tube, but not in the bulb. In the square tube the discharge passes along the lines of magnetic force and is helped; in the bulb it passes across them and is retarded.

A NEW MINING MOTOR.*

BY HENRY A. MAVOR.

(Concluded from page 107.)

Now, unfortunately, the substances which are suitable for insulating or confining the current to the conductors are none of them metals, and are not suitable for transmitting mechanical strain. It is for this reason that so much difficulty has been found in making motor armatures thoroughly sound in mechanical construction.

There is no doubt that experience has shown that the most satisfactory method of mounting the conductors is to place them in channels in the iron core as shown in Figs. 5 and 6. The common method of simply binding them to the smooth surface of the core has often led to trouble from the shifting of the conductors on the surface. That method would never have been adopted but for other difficulties, again electromagnetic as distinguished from mechanical, but which are fortunately rather a matter of ancient history than of practical present-day importance. There are other mechanical details applied to the construction of the motor which is more specially under our notice to-night which have done much to make the armature more satisfactory. Chief among these is the method of putting on the wire.

The usual method of winding such armatures is to start with a single conductor, and wind it by hand on the core from end to end. This is a most laborious process, which has the further disadvantages that the first turn of wire is covered up by all the succeeding turns, that the first turn to go on to the shortest, and the last the longest, no two turns being exactly the same length, while in the ends of the armature the wires are heaped up in a most unmechanical fashion. (The Gramme or ring winding is free from some of these defects, but has to be carried out entirely by hand.)

The method adopted in the machine under consideration is to wind in a separate former a coil for each slit in the core. These formers are wound in the lathe, and are all precisely similar in every respect. These separate coils are then set round the core, one in each slot, and are driven down to the bottom of the slot, one side of the coil half filling the slot, and the other side standing up above the periphery of the core. The projecting sides of the coils are then grasped simultaneously by a suitable tool, which keeps them in a fixed position, and the core is turned round through a half circle. The coils are thus twisted round, so that the projecting half comes to be diametrically opposite the half which has been embedded in the slot. The tool is then removed, and the projecting wires are slipped into the slots lying beneath them, and the main winding of the armature is complete, making a perfectly mechanical and symmetrical job, easily accessible for repair, and readily open to inspection. Two difficulties are thus overcome. A perfect positive mechanical drive is obtained for the conductors, and the mechanical difficulty of insulation is much reduced, because, instead of an indefinite number of possible points of contact between wire and wire, and between wire and core, we have a fixed number of places requiring protection, and these places are all in similar positions, so that the omission of the necessary protection can be determined by inspection. One of the chief difficulties to be overcome in all continuous-current electric motors is the tendency to spark at the brushes which transmit the current by the commutator to the moving conductors of the armature.

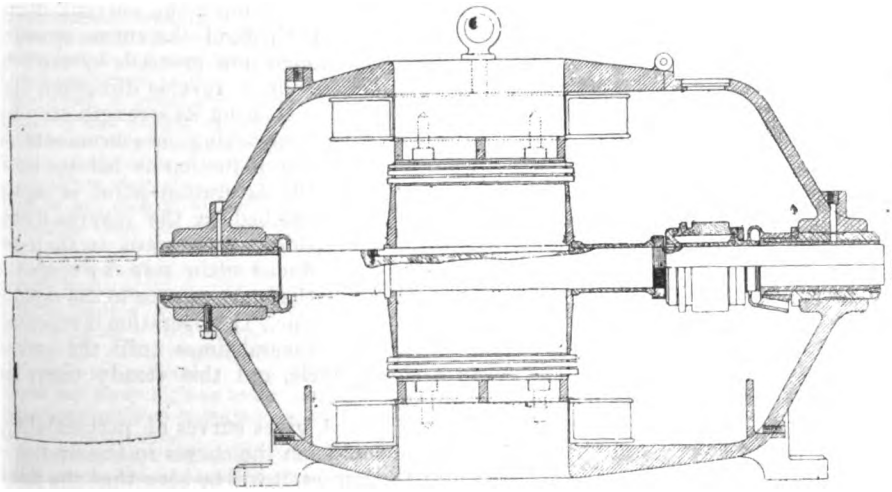

FIG. 5.—Longitudinal Section of Enclosed Type Motor.

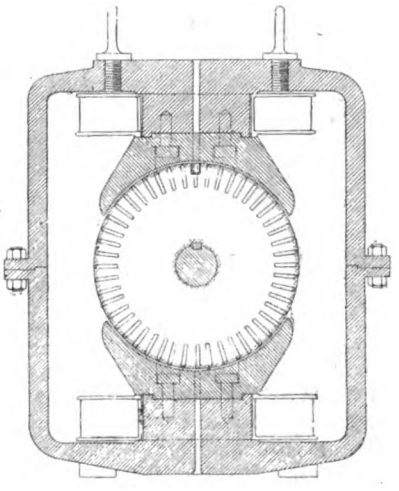

FIG. 6.—Cross-section.

* Paper read on December 18, 1894, before the Institution of Engineers and Shipbuilders in Scotland, and printed in the *Transactions* of the institution.

Digitized by Google

Even in well-designed motors sparking is liable to occur with changes of load. This can be got rid of to a large extent by changing the position of the brushes with change of load, but it is not always convenient to do this, especially in motors used for intermittent work, such as hauling or coal cutting. A device invented by Mr. W. B. Sayers, and well known to electrical engineers, has, to a large extent, got over this difficulty, and experience in its use will probably enable motor-builders to design and construct motors of any size which will run sparklessly at any load without any necessity for changing the position of the brushes. The explanation of the action of this device is too complicated and technical for others than specialists in this work, and it will be sufficient to say that it has been successfully applied to machines up to the size of machine shown in the diagram, with perfectly satisfactory results as regards sparking, the brushes remaining fixed for all loads. Formerly considerations in connection with sparking fixed a limit to the air space or gap between the magnets and armature, so that this could not be reduced to the dimension otherwise desirable. The use of this device has enabled us to reduce the air-space to the very small dimension shown in the diagram. The effect of this shortening of the air-space will be at once evident from what has been said about the magnetic field—the intensity of the magnetic field, or group of magnetic whirls, set up by the conductors wound on the field magnets, depending on the nature of the substances which form its path. Iron increases this intensity, while air does not; therefore, the less air there is in the path, the less magnetising force will be required. This means that less current need be sent round the magnets, and, therefore, that less space is required for wire. It is this primarily which has enabled us to make a practical motor entirely enclosed in metal, and yet which is not excessively heavy or unwieldy. This has been made still more attainable by the advent of what is practically a new material. In the old days, cast iron was the material principally used for field magnets. The researches of Dr. Hopkinson and Mr. Gisbert Kapp demonstrated, without doubt, that dynamos ought not to be made of cast iron, and wrought iron for many succeeding years held the field. This is now destined to give way before steel, so called, which is really chemically pure iron, obtained by the process used for making steel. To enable me to illustrate the advantage of using this material, I will endeavour to give you a slight outline of the nature of the differences of these substances in the property of intensifying magnetic whirls, or stream lines, which, as we have seen, is an essential and vital element in the construction of dynamo-electric machinery. The diagrams which have been placed in your hands are intended to illustrate this property in different materials. See Figs. 7 and 8.

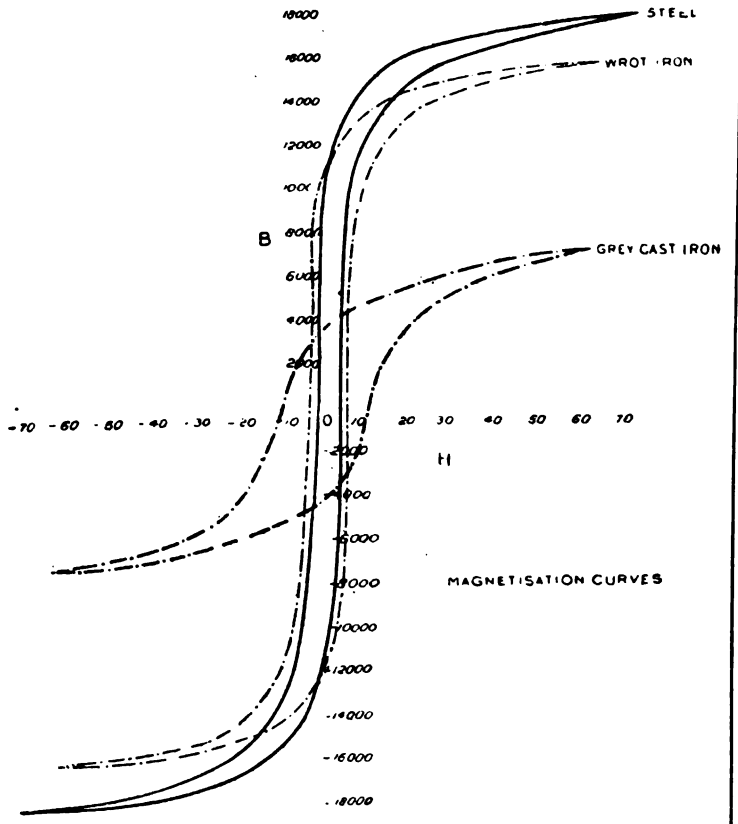

Fig. 7.

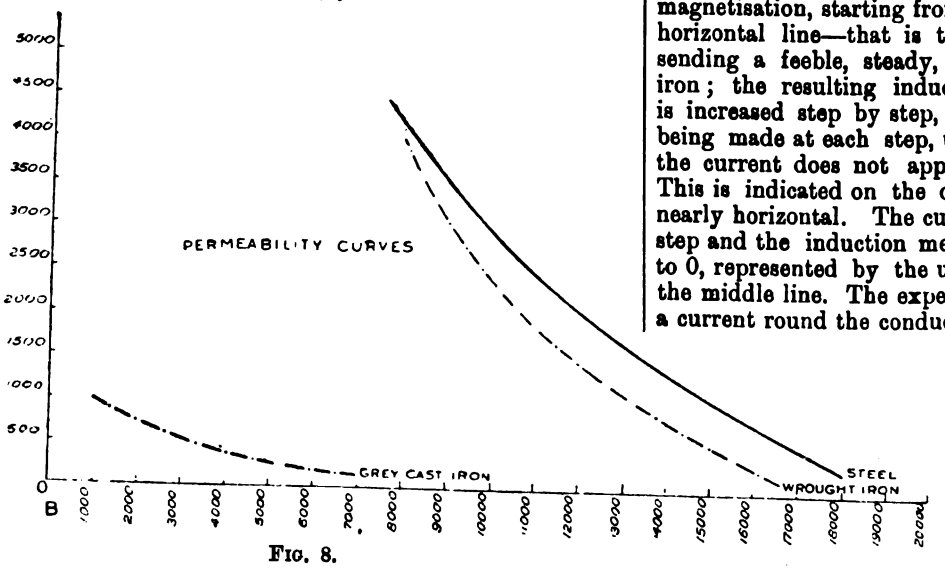

Fig. 8.

The two smaller curves, Fig. 7, are taken from those published by Messrs. Krupp. They are tests of grey cast iron and of wrought iron, which seem to have as good magnetic properties as any which have come under my notice. The largest curve, Fig. 8, is taken from those published by Messrs. Allen, of Sheffield, and is the result of independent experiments by Prof. Jamieson and Prof. J. A. Ewing, which are so nearly in agreement that the curves given by those two distinguished experimenters are practically identical.

The abscissæ, H, in this curve represent the magnetising forces produced by electric currents made to circulate in a conductor wound round the iron; the ordinates, B, represent the resulting magnetic induction. It will be seen that the curves are double, enclosing in each case an area.

The curve in each case represents a complete cycle of magnetisation, starting from and returning to the middle horizontal line—that is to say, the experiment starts by sending a feeble, steady, continuous current round the iron; the resulting induction is measured, the current is increased step by step, measurements of the induction being made at each step, until it is found that increasing the current does not appreciably increase the induction. This is indicated on the diagram by the curve becoming nearly horizontal. The current is then decreased step by step and the induction measured until the current drops to 0, represented by the upper part of the curve crossing the middle line. The experiment now proceeds by sending a current round the conductor in a reverse direction, and increasing its strength step by step, taking measurements of the induction as before until the saturation point is again reached in the reverse direction; the current is then reduced again step by step till the curve returns to the middle line. This operation is repeated several times until the curves settles down to a steady cycle, and this steady curve is shown on the diagram.

The other diagram, Fig. 8, gives curves of permeability, or the ratio, B/H, deduced from the curves in the first.

Looking, now, at the curves, it will be seen that the magnetising force, H, produces in cast iron a much smaller induction than in wrought iron or in steel; further, that the amount of induction, B, resulting from a given magnetising force, H, varies at the higher parts of the curve according to preceding magnetic condition in the cast iron very much more than in the wrought iron or steel; that wrought iron and steel are capable of magnetisation to a

Digitized by Google

much higher degree; and again, that the energy required to produce a reversal of magnetisation in cast iron is much greater than in steel or wrought iron. All these peculiarities are disadvantageous, and, therefore, the use of cast iron for the parts of the motor subject to reversals of magnetisations has practically disappeared, and in all other parts has almost completely given way to wrought iron or steel. The steel has the special advantage that, while it has magnetic properties even superior to wrought iron, it can be cast into any desired shape and still retain its magnetic properties.

These considerations led to the adoption of steel for the magnets and case—the case also forming part of the magnetic circuit—of the motor in question.

B in the curves representing the induction per square centimetre of the metal, it will be seen that for a given total induction the steel need be much smaller in section than cast iron, and H representing the magnetising force per centimetre length, the reduction of magnetising force and consequent reduction of space for the conductor to carry the magnetising current, leads to a still further advantage.

It will thus be seen that the use of steel has not only increased the efficiency of the motor by reducing the necessary magnetising force, but by reducing the size and labour in tooling has also reduced the cost of production, while the use of a short air-space has made it possible to entirely enclose the motor without seriously increasing its weight. The enormous advantage of this will be at once apparent. Dust, damp, and explosive gases are entirely excluded from the working parts, while the increased radiating surface seems to compensate entirely for the less efficient circulation of air.

There seems every reason to expect that this machine has an important future in its application to mining.

DISCUSSION.

Mr. A. W. Stewart, who opened the discussion, thanked Mr. Mavor for the very lucid description he had given of his motor, especially to those who did not know much about the way the torque was given to the armature. He thought the description was one of the clearest he had ever heard. He asked Mr. Mavor if there was no trouble from sweat or moisture inside the shell. In a changeable temperature like a coal pit, a good deal of moisture would be dropping about the connections, and would develop short-circuits and other troubles. He would also like to ask him if he had tried anything in the way of alternating currents as applied to this motor. He understood that Mr. Brown, of the Oerlikon Works, had designed and had actually motors working now, called three-phase motors. These motors had no brushes or commutators, and worked with a very high efficiency, and so got over the difficulty that everyone who had worked with commutators must know about—the sparking of the brushes and the wear of the commutator. This was certainly a big step in advance to do away with commutators. Anyone who had been working with them knew that not only the wear of the commutator was a great nuisance, but also the breaking of the connections of the coils on the armature to that commutator. They gave incessant trouble in the best-designed motors.

Mr. Samuel Mavor said that with regard to the efficiency of transmission of power for colliery working the efficiency might be a very important point, but there were other considerations which were often a great deal more important than efficiency. The difficulty and danger of carrying steam down a pit and along the roads were very great; the loss was also very great, and there was always the trouble of keeping the joints tight, with the result that leaky joints were always in these pipes, and the roads were kept more or less choked with steam. The electric motor required less attention than the air or steam motors, so that in a pit where rope or steam transmission was used there were often small pumps where two, or three, or four men were working by hand, simply because the cost of the steam or rope transmission to those distant pumps would be so very great. One man paying the electric motor a visit on each shift for oiling was quite sufficient to keep the thing in good order, so that he might point out that although the efficiency for comparatively short transmissions might not be so high as some might expect, other considerations were frequently so important as to lead to the adoption of electrical transmission.

Mr. John Barr asked Mr. Mavor to state whether there was a small proportion of carbon in the field magnets, whether they were cast steel or hammered afterwards. The drawing showed a double brush where the spindle worked through the cast-iron casing, and he presumed it was made thus for replacement. He thought the efficiency of these motors was a very important point. It would be interesting if Mr. Mavor could tell them what ultimate efficiency he got, say, from a set of pumps driven by a motor in practical everyday work—*i.e.*, taking into account friction of steam-engine dynamo heads, motor, and pumps, leaving out the friction that might occur between the pump and the surface.

The discussion was then adjourned to the next general meeting

NEXT WEEK'S NEWS TO-DAY.

The Institution of Mechanical Engineers met yesterday evening for the reading and discussion of papers. The proceedings will be resumed this (Friday) evening.

A correspondent of the *Globe* writing from Gibraltar states that telegraphic communication is interrupted in Spain, as also on the Eastern Telegraph Company's cables to Tangiers and Cadiz.

The famous engineering works at Madgeburg, where electric motors are largely used, have just lost their principal in the person of Herr Gruson, who was yesterday reported to have died there on Wednesday evening.

Mr. James Bryce, the President of the Board of Trade, occupied the chair yesterday afternoon at the adjourned conference on light railways. The report of the committee, which is referred to in another column, was adopted.

An explosion is reported to have occurred at Dover yesterday (Thursday) morning in a transformer-chamber or junction-box. The explosion is attributed to an escape of coal gas. This report seems rather strange, seeing that the company have not yet commenced to supply light.

Dealing with the difficulty which has arisen in the law courts in regard to the positions and duties of some of the judges, the *Pall Mall* yesterday stated that "there is another aspect of the imbroglio which so far has been overlooked. Engineers, electricians, chemists, and others who have patent and technical cases to try, in short, scientific experts generally, are aggrieved that Mr. Justice Romer has been taken away from their work 'to serve tables,' so to say. They have the fullest confidence in him, and many declare that they prefer him without a jury to any tribunal in the kingdom. He seizes the point in a moment, measures the value of expert (that is, contradictory) evidence, and gives most lucid decisions—just what might be expected from an ex-Senior Wrangler. Litigants of the class referred to like a judge who knows, and who uses his knowledge, and is not afraid of giving a firm decision. His was the only equity court for the continuous trial of actions with witnesses—mostly of the expert class, who are now crying Ichabod."

Discussing the Great Northern and City (Electric) Railway Company's prospectus, the *Pall Mall Gazette* yesterday stated that, "It is not clear what arrangement, if any, the Great Northern Railway has made with the Metropolitan and North London Companies in connection with the formation of the new electric line, over which it will run trains from Finsbury Park to Moorgate-street. At present all its trains are run thither over the Metropolitan system, and for using that system the Moorgate-street and the North London system to Broad-street it pays these two companies about £25,000 and £30,000 a year respectively, varying with the traffic. The new line must divert an immense amount of this traffic, for a glance at the map will show that few passengers will care to travel from Finsbury Park to the City right round by King's Cross or right round by Dalston, when they can reach it direct by the new line. It looks as if a hole in the receipts of the Metropolitan and the North London must be made when the new line is used."

Electrical Engineer's Training.—The educational fad of the moment is electrical engineering, just as some years ago every man thought he must make his boy a civil engineer. Mr. James B. Cahoon, than whom there can be no better authority in the United States, tells us in the January number of *Electric Power* how this training must be supplemented in order to make a real electrical engineer. One important suggestion of Lieutenant Cahoon's is the training in moving heavy machinery into place.

OVERHEAD WIRES.

Charles Kingsley is considered to have been an apostle of the bracing effects upon human beings of east winds, such as we know too well in the otherwise merry spring time. Doubtless there are those who enjoy the cold buffeting of Nature, just as many may be found hardy enough to break the ice for a morning dip; but when all is said and done, the fact remains that the strong alone can revel in hardships: the weak are generally shrivelled up. It is with no little pleasure that we can express absolute confidence in the electric traction interests so far as concerns their ability to withstand and ultimately overcome with ease the metaphorical cold blasts poured upon them just lately by the London County Council. The facts of the case are so clear, and the cause involved of such manifest justice, that the electric traction industry may well feel certain of successfully erecting the trolley wire, despite the opposition that is brought to bear from those who are either prejudiced or unaware of the true circumstances.

It is needless to attempt—in these pages—the least refutation of the statements made at the meeting of the London County Council on Tuesday last with reference to the application from the London United Tramways, Limited, for approval of an overhead wire system in the West of London. Every single one of our readers will recognise the ridiculous and childish nature of the objections raised—whether it be the absurd suggestion that the lines might be used to hang clothes upon, or would keep from the inhabitants of the district a large portion of the blue sky and sunshine for which London is so proverbially famous! How much difference can a quarter-inch wire make in any case?

We are not surprised at expressions of disapproval coming from many members of the London County Council, in view of the grandmotherly way in which Londoners were preserved from sky-signs that with all their hideousness were no worse looking than the average London chimney. It is charitable to hope that none of those who opposed the overhead wire proposal can ever have seen a trolley road of reasonable design at work, or listened attentively to promoters' statements, otherwise we should have to accuse them of absolute unfairness to a perfectly sensible method. It is not proposed, and never has been, that the exact trolley system as used in the United States shall come into employment here. Considerable improvements have been made in it which afford reliable grounds for stating that the overhead wire must be adopted or none at all. It is absolutely useless for the County Council to talk of electric traction as an excellent thing, but—overhead wires must not be employed. Alike on the score of cheapness in erection and working, they stand far above any other possible method of employing electricity as the motive power; and they afford all the advantages of low fares, rapid transit, perfect safety, and greater cleanliness, that are so desired and essential for modern requirements.

What, however, shall be thought of a journal like the *Pall Mall Gazette*—a paper that has done

Digitized by Google

yeoman service in the exposure of electrical frauds—commenting upon the proposal above named in the manner that it does? The idea of "spoiling London streets by the erection of pillars and wires" is really too absurd for anything, even for a *Pall Mall* young man. We should like to find a single street in this London of ours where a line of tramway now runs that could in the least be rendered more atrociously hideous and ugly than it now is, thanks to the jerry builder and his *confrères*. If the *Pall Mall* wants to Hausmannize London, it should begin by taking the people further afield, by putting an end to the unhealthy and immoral crowding of families into small dens at fabulous rentals; then the buildings of the future may have a better appearance and do more justice to the metropolis not only of England, but of the world.

How can this better be done than by affording every possible means of rapid transit whereby the suburbs are rendered more easy of access, and the necessities of life—fresh air, sunshine, open spaces, and reasonable house accommodation at low rents—secured even to the poorest of the poor? Perhaps the London County Council or the *Pall Mall Gazette* will kindly answer our question.

LIGHT RAILWAYS.

The report of the Committee of Conference on Light Railways was issued yesterday (Thursday) afternoon. The report, which pressure on our space prevents publication in this issue, is accompanied by several appendices from individual members of the committee, although on the whole the committee are practically unanimous in their recommendations. The committee believe that the impediments to the construction of light railways may be greatly diminished, and that on a large proportion of such lines as are contemplated by their enquiry, the regulations which have been enforced with a view to public safety may be considerably relaxed. The committee state that the recent establishment of popular local authorities opens the door to an escape from the great cost attending applications to Parliament by enabling powers with reference to the authorisation and control of light lines to be conferred on those bodies. If this were done the committee consider that the initial cost of construction, and the expense of working, could be so greatly reduced that many light railways and tramways could be undertaken to the advantage of districts at present without satisfactory means of transport. Proposals for the construction and operation of such lines, the committee suggest, should be first submitted to the County Council. In conclusion, the committee express doubts as to whether it is desirable that local authorities should be empowered to contribute funds towards, or otherwise take part in, undertakings of this nature.

We understand that a Bill is very shortly to be brought into Parliament with a view to crystallising the results of the committee's investigations; and the probability is that substantial progress will now be made in traction matters, though not necessarily on a large scale at first, or on plans at all resembling those in vogue abroad.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTRIC TRACTION.

SIR,—In a paragraph in your issue of last week on the recent discussion on "Mountain Railways" at the Institution of Civil Engineers, it is stated that at the meeting of January 22 several speakers referred to electric traction, and that one went so far as to maintain that electrical working ensured a saving of 50 per cent. as compared with steam locomotives, albeit, in your opinion, this probably only applies to cases where water power is available.

The two speakers who, during the whole discussion, referred more especially to electric traction were Dr. John Hopkinson and myself; and as it was I who made the statement quoted in your paragraph, I may say that the saving of 50 per cent., which I have over and over again proved in various papers and by comparisons founded on my own experience, is by no means limited only to installations driven by water power, but applies equally to cases where the dynamos are driven by steam-engines; and further, that it applies equally to steep-grade and to level lines.—Yours, etc., C. S. DU RICHE PRELLER.

18, Margaret-street, Cavendish-square, W.,
January 29, 1895.

ELECTRIC BRAKE COUPLINGS.

SIR,—Mr. Bushell's double-barrelled enquiry in your last week's issue is not very clear—is not, I may say, at all clear—and I would personally be glad if he can explain what it really is that he wishes to know. If he refers to the type of coupling required between adjacent carriages of a train fitted with any system of electric brakes, he need wish for nothing better than that employed on trains lighted by electricity. A simple spring jack-knife arrangement serves every requirement in this direction. If, however, he refers to the mechanical couplings which connect in some systems the magnetic braking device with the car axles or wheels, then he will need to specify which of these he has in view.

I can hardly suppose that he wishes to know the best coupling for ordinary brakes on electric railway trains, but his expression "electric railway brakes" is too indefinite to deal with as it stands.

The second part of his query is also very vague: there have been (I use this tense advisedly) as many electric traction companies as leaves in Vallombrosa. Which of them does he mean?—Yours, etc., FRANK B. LEA.

London, January 30, 1895.

AN ANGLO-AMERICAN CABLE.

In addressing the shareholders of the Anglo-American Telegraph Company, the chairman's remarks on the condition of these cables are reported as follows in the *Financial Times* of the 26th ult.:

"The 1873 and the 1880 cables were in fair condition, and the 1874 cable, which was repaired last year, was also in good condition, with this reserve, that it was interrupted in about 100 fathoms of water on the Irish coast."

In our last issue we published an extract from a Boston newspaper in which the 1874 cable is referred to, and from which it would seem that to look on this cable as in good condition (even while excepting the present break) shows a very sanguine temperament. For the benefit of our readers we reprint from the extract that portion which refers to the 1874 cable:

"In the meanwhile the 'Calabria,' double the size of

Digitized by Google

us, had gone to repair the 1874 cable. She started in July, and was over 100 days at it. Once during that time she lifted one end, spoke the shore, and spliced one piece of new cable. When they commenced to pay out the cable broke, and, if my memory serves me right, it was on board ship. They lost it, and never recovered it again for that year. It sunk in 2,400 or 2,500 fathoms of water. There's one example for you. In October I was in St. John's and was ordered to proceed to England, I having told the manager that it was impossible to recover the cable that year. The 'Calabria' also went to England, the manager having agreed to what I said. All they had done was to break pieces off."

UNDERGROUND MAINS AT NOTTINGHAM.

In our issues of February 23 and March 2, 1894, we gave a description, together with several illustrations, of the central electric light station erected for the Nottingham Corporation between Talbot-street and Wollaton-street. The supply of light was commenced in September last, and since then the working of the station has proceeded satisfactorily.

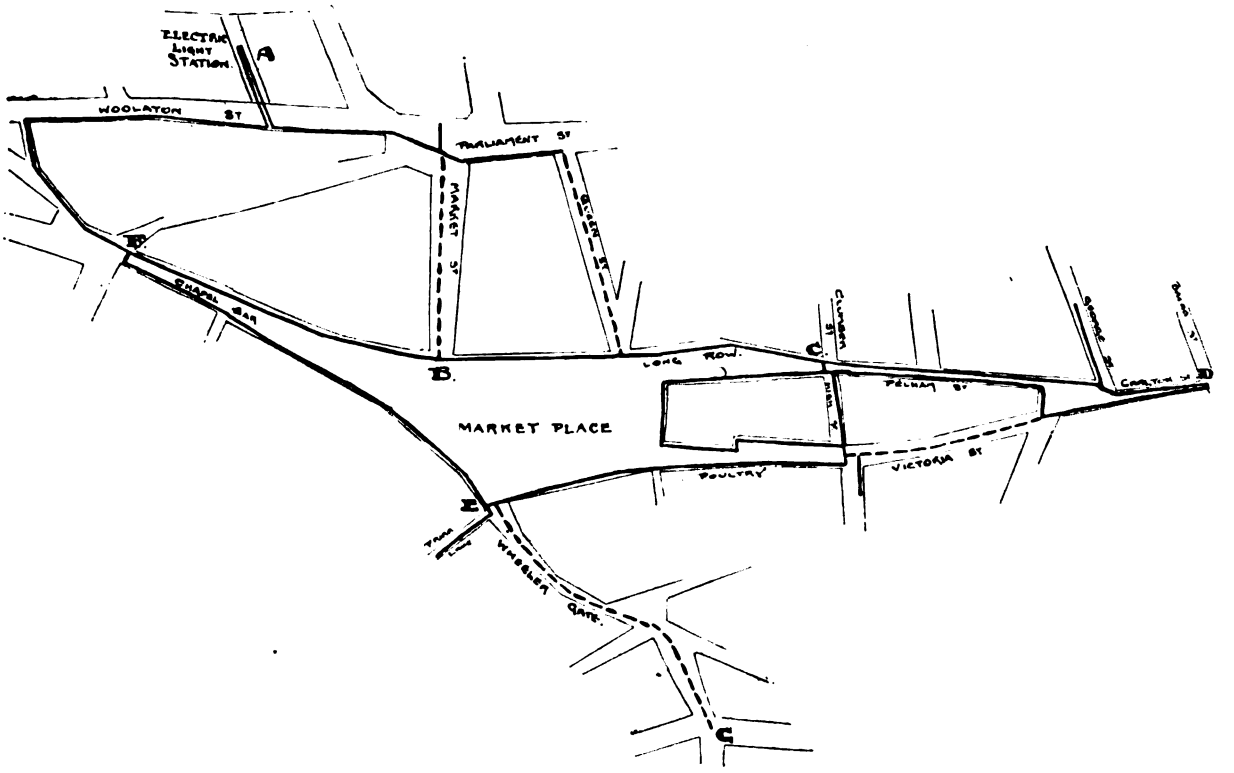

FIG 1.—Plan, showing in Continuous Lines where Conduits have been Laid, and in Dotted Lines the Subways containing Mains.

Some details concerning the underground mains will be interesting at the present moment, more especially as Nottingham is the first town in this country where any attempt has been made on a fairly large scale to utilise subways for the accommodation of the mains. It must not be inferred from this that all the mains are placed in subways. Some of them are carried in subways, whilst in other cases they are placed under the footpaths. The annexed plan, Fig. 1, shows the route followed by the feeders and distributors; Figs. 2 and 3 represent the laying of the conduits in different streets; and Fig. 4 shows the arrangement adopted of carrying the mains in the subways.

The contract for the whole system of distribution outside the station was placed in the hands of Callender's Bitumen, Telegraph, and Waterproof Company, Limited, of 101, Leadenhall-street, London, E.C. The specification provided that a drawing-in scheme should be used with cables on the three-way system, but it allowed great latitude in the choice of the details. After examining various offers the tender of the Callender Company was selected, and the system known as the "Callender-Webber conduit" was decided upon.

The Callender-Webber conduit consists of blocks of bitumen concrete made in 6ft. lengths and ways, varying in number and diameter to suit the requirements of the several lines. These cases are joined together on the work into continuous conduits, and access is gained to them for the purpose of handling cables (which are afterwards drawn in) from brick manholes. The diameter of the ways of the feeder casing is 3in. throughout almost the whole length, a few of the smaller sections having $2\frac{3}{8}$in. ways. The distributing network has ways of either 2in. or $2\frac{3}{8}$in., according to the size of cable employed. Spare ways have been left on each of the feeder lines, so that additional cables can be drawn in or new feeders can be provided to other points in the town when necessary. The casing throughout, both for the feeder lines and for the network, has been designed so that every way is large enough to take a cable of double the sectional area of that now drawn into it.

The brick pits are placed at each street corner so as to give immediate access to the cable wherever it is under the roadway, whilst others have also been constructed at different points under the footpath where they will be most necessary for drawing in the cable. Six extra large-sized manholes are provided at the points shown on the accompanying map, Fig. 1. These are used for the feeding points, and they have a clear opening of 24in. by 32in. Where the conduit has a large number of ways—*i.e.*, where the feeders and distributors run together—the drawing-boxes, of which there are 15, have a clear open space of 24in. by 18in. On the lines which consist only of distributing cables, the boxes, of which there are 40, are smaller, with 18in. by 12in. openings. All the boxes are provided with surface frame and a double cover, the inner cover being of cast iron, and so arranged as to form a watertight seal to the box. The outer cover is faced with concrete so as to resemble the paving in the adjoining streets. The pits are constructed of best wire-cut bricks set in cement, but the floor of the box is of loose brick rubble, so that any water which may by chance get into the pit will have every facility of draining away.

The adoption of this system does not necessitate arrangements being made for connecting services until they are actually required. Each individual customer is then easily connected with the mains, the casing being cut away and a small brick hand-hole built round it. These service-boxes have a frame and cover plate, so that the connections can be easily inspected.

At present, conduits have been laid in those streets shown by a continuous line on the accompanying plan. The

Digitized by Google

dotted line indicates the subways in which mains have been placed. There being ample space in the subways, cast-iron brackets have been attached to the walls at convenient heights, and the cables have been payed into position and so held by bitumenised wooden blocks, which are gripped inside the brackets. The photograph of the subway shows the arrangement adopted.

The whole of the cables used are made as follows: The strand is of copper of 100 per cent. conductivity, tinned, and then stranded. It is braided with fine yarn and compounded, and is then insulated by means of a solid sheath of vulcanised bitumen put on at one operation under pressure. This core is twice taped, then served with yarn and well compounded, and finally braided with flax yarn and dressed with preservative material. The sectional areas of the feeders are

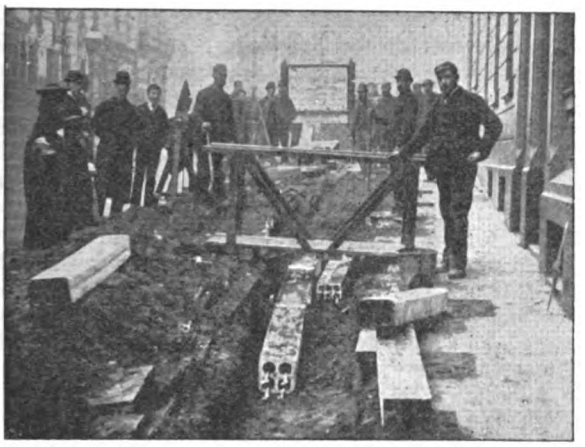

FIG. 2.—Laying the Mains.

·80 square inch, ·75 square inch, ·60 square inch, ·50 square inch, and a short line of ·25 square inch. The feeding cables to four of the feeding points consist of two outer conductors only, the connection between the third wire of the network and the generating station being made by the feeders at B and E only.

The distributing network consists of three cables, the centre wire being one-half of the sectional area of each of the outers, the largest of which consists of cables of ·25, ·125, ·25. In some of the heavier streets the sectional area is increased to ·30, ·15, ·30, whilst in some of the small lanes it is reduced to ·125, ·062, ·125.

FIG. 3.—Laying the Mains.

The total length of street in which mains have been laid is about 3,400 yards. In this distance there are 10¾ miles of case ways, and the accommodation in the subways equals 4½ miles of case ways. Into this about 10 miles of cable are joined together by copper bars at the various points where they interlace. These bars are so arranged that any line can be disconnected from any other with the greatest rapidity. The bars are insulated with bitumen compound, so as to prevent them from being influenced by damp or water. In addition to the main cables, pilot wires are provided from the station to each of the feeding points; these are separate vulcanised wires, each ·3, No. 18, on each pole, and that to each pole is drawn into the same way as the cable supplying that pole.

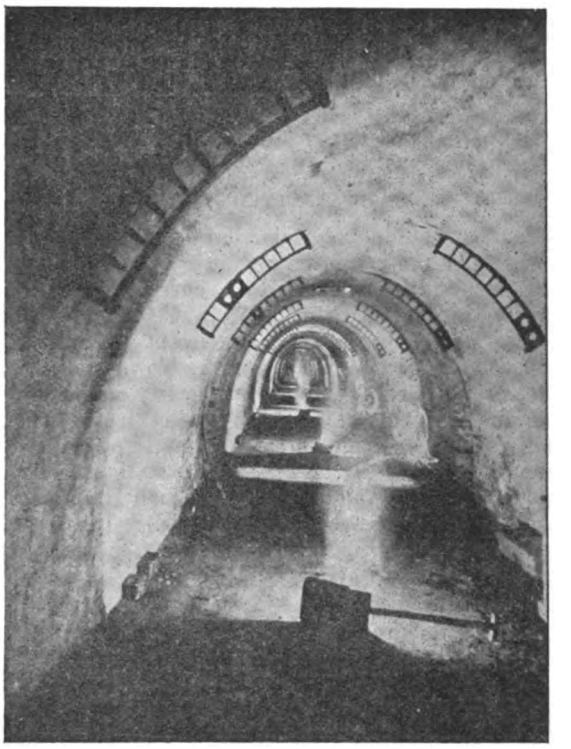

FIG. 4.—Arrangement of Mains in the Subway.

The contractors state that the plans were so carefully prepared by Mr. H. Talbot, the resident electrical engineer, that the quantity of casing and of cable used was found to tally with that estimated to within a few yards. No alterations whatever have been made in the original plans, but several extensions have already been necessary. The excavation of the trenches and the reinstating of the pavement were carried out by Corporation officials; but the whole of the other work was in the hands of the Callender Company, under the direction of Mr. Douglas Reid, their resident engineer, assisted by Mr. A. Burton. The station buildings, it may be mentioned, were designed by Mr. Arthur Brown, M.I.C.E., the borough engineer, and the electrical plant by Mr. Talbot, who also superintended the erection of the machinery.

WOLVERHAMPTON ELECTRICITY WORKS.

The ceremony of formally switching on the lamps supplied from the Wolverhampton electricity works was performed by Lord Kelvin on Wednesday afternoon. Among those present to welcome his lordship were the Mayor (Alderman C. T. Mander); Aldermen Saunders (ex-mayor), S. T. Mander, and Jackson; Councillors Jenks, Ironmonger, Pinson, McBean, Allen, Johnson, J. J. Tate, and Craddock; the Town Clerk (Mr. H. Brevitt); Messrs. Thomas Parker, A. B. Blackburn, J. Thompson, A. P. Brevitt (the architect), and H. Willcock (the builder). Mr. F. Harman Lewis, A.M.I.E.E., the borough electrical engineer, was, we regret to state, unable to be present, owing to an accident.

The station has been carried out according to the revised scheme prepared by Mr. Lewis, who was appointed electrical engineer to the Corporation in May, 1893, Mr. A. P. Brevitt, of Wolverhampton, being chosen as architect. It may be mentioned that Mr. R. E. W. Berrington, who is the borough engineer, reported on the subject of electric lighting two or three years previous to the appointment of Mr. Lewis. As a result of the advice given by Mr. Lewis, the Corporation in December, 1893, accepted the following tenders:

Buildings	H. Willcock and Co.
Boilers, economisers, and feed pumps.....	J. Thompson, Wolverhampton.

Digitized by Google

Engines, condensing plant, dynamos and exciters, motor generators and switchboards	Electric Construction Company, London.
Mains	Callender's Bitumen, Telegraph, and Waterproof Works Company, Limited, London.
Arc lamps	Johnson and Phillips, London.
Lamp standards	Bailey, Pegg, and Co., Brierley Hill.
Accumulators	Epstein Electric Accumulator Company.
Overhead traveller	Bedford Engineering Company.
Water softener	Stanhope Water Engineering Company.

The Adopted System.

The system adopted is similar to that introduced at Oxford, with the exception that it is at 2,000 volts instead of 1,000. The high-pressure direct-current generating plant is erected in the station situated in Commercial-road, outside the area of supply. The current is transmitted at 2,000 volts to a switch station at the Town Hall, about the centre of the area of supply and nearly one mile distant, by means of trunk mains. At this centre the current is sub-divided by switching arrangements into smaller quantities, and conveyed by feeders to sub-stations. There are three sub-stations, one being at the Town Hall, a second at the Art Gallery, and the third at the Free Library. Motor generators are arranged in these sub-stations, transforming the current down to 110 volts.

The Station.

The station buildings occupy an area of 4,066 square yards, and the nature of the site selected will permit of extensions being made to nearly three times this area. The total area of the site is about 12,400 square yards, extending from the Birmingham Canal to the Commercial-road.

The boiler-house, which is 81ft. long by 50ft. wide, contains three Lancashire boilers, 30ft. by 8ft., fitted with Galloway tubes and Caddy's firebars, hand-worked. The pressure is from 120lb. to 130lb. per square inch. There are two Green's economisers, with extra foundations for an additional two, and two Cameron duplex feed pumps. The chimney stack, which is 120ft. high by 5ft. 6in. internal diameter, is capable of working five or six boilers equal in size to the present. The feed water is taken from the town mains, and is softened by being mixed with lime and soda, and then led into a cast-iron tank.

The engine and dynamo room is 79ft. 6in. long by 55ft. wide, and is spanned by a hand-worked travelling crane capable of lifting five tons. The plant installed consists of two 250-h.p. Marshall engines driving, by 15 1½in. ropes, two 132-kilowatt dynamos and their respective exciters, and one 125-h.p. Marshall engine driving, by eight 1½in. ropes, a 66-kilowatt dynamo and its exciter. A switchboard, of black slate panels, is provided in an oak frame, fitted with main switches and regulating resistances, and controlling devices for working the accumulators are placed along the top wall of this room.

The engines are of the horizontal compound-condensing type. Steam is admitted into the high and low pressure cylinders by Pröell's automatic trip valves placed upon the top of each cylinder, and in each case exhausted through Corliss valves fitted upon the under side of each cylinder. The automatic gear is controlled by Pröell's governor, which is extremely sensitive, being fitted with a speed-adjusting arrangement, so that the speed of the engine may be varied 5 per cent. either way whilst running.

The principal dimensions of the two 250 h.p. engines are: high-pressure cylinder 14½in. diameter, low-pressure cylinder 25in. diameter, and length of stroke 32in.; the flywheel is 14ft. diameter. The 125-h.p. engine has a high-pressure cylinder 10in. diameter, low-pressure cylinder 17½in. diameter, and a stroke of 24in.; the flywheel is 9ft. diameter. The dynamos and exciters are of the Elwell-Parker type.

The main steam-piping is 6in. wrought iron, with the necessary copper bends inserted, and valves of Hopkinson's double-faced slide type. The draining of the main pipe ring is effected by means of Royal's automatic steam-traps. The ring rests upon rollers, supported by standards in the boiler-house, and is suspended from brackets, by hangers, in the engine-room. The condenser is of the Ledward type, this being used with a centrifugal pump, coupled direct to the crank of a Chandler high-speed engine drawing its water from the canal. The circulating with the condensed water gravitates back to the canal. The steam has an alternative exhaust into the atmosphere 60ft. above the floor line. The cast-iron main exhaust is 14in. diameter, and is placed in a trench below the floor line, and is covered over with chequered plate.

Sub-Stations.

A sub-station and a central switch station combined are arranged at the Town Hall. It contains two lighting transformers, an arc-lighting transformer, and a battery-charging transformer. The switchboard has black slate panels arranged in an oak frame and fitted with switches, resistances, and automatic devices for working the distant sub-stations, home transformers, mains, and regulating the batteries.

The Free Library and Art Gallery sub-stations are each equipped with one lighting transformer and automatic switch controlled from the central switch station. Each sub station is fitted with a small two-ton travelling crane.

The Mains.

The high-pressure trunk and feeder mains are laid in cast-iron troughs, being supported from the metal by wooden bridges, and then completely surrounded by bitumen run in hot. The method adopted is Callender's solid system. The arc light concentric telephone and pilot wires and the distributors are lead covered and steel sheathed, and laid direct into the ground. The length of the mains is nearly one mile of high-pressure trunk main, one mile of high-pressure feeder main, two miles of arc light concentric, and over 2½ miles of low-pressure distributor for consumers' lighting.

Up to the present, 59 applications for the supply of electrical energy, representing 4,161 8-c.p. lamps, have been received. The total cost of the undertaking has been £25,019.

THE INCANDESCENT LAMP.*

BY MANNING K. EYRE.

To describe at short notice for the non-technical reader and in a limited space the manufacture of incandescent lamps is not as simple a task as may appear, and I therefore beg the forbearance of the reader if the result proves, as I fear it may, uninteresting and incomplete.

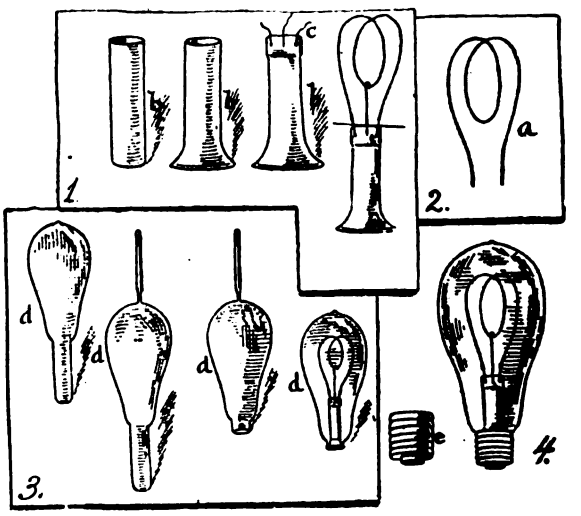

FIG. 1.—Part of an Incandescent Lamp.—1. Showing Steps in Manufacture of "Inside Part."—2. Filament.—3. Showing Steps in the Manufacture of Bulb.—4. Base and Finished Lamp.

The manufacture of incandescent lamps consists in the manufacture, manipulation, and final assembling of the five distinct parts which constitute a finished lamp. The total number of operations necessary in the construction of the lamp is in the neighbourhood of sixty-five. It is needless to add that in the space of this paper it is not only impossible to fully describe any process, but many of them

* The *Electrical World* (New York).

Digitized by Google

can only be indicated. The five parts of the lamp above referred to are, *a*, the filament; *b*, the inside part; *c*, the leading-in wires; *d*, the bulb; and, *e*, the base. These appear in Fig. 1, and are there indicated as *a*, *b*, *c*, *d*, *e* in the order named.

The filament, or, as it is commonly called, the carbon, is that part of the lamp which in offering a resistance to the passage of the electrical current is thereby rendered incandescent, and emits heat, which is waste, and light, which is useful. The history of the development of this insignificant-looking thread is the history of some of the best years of such men as Gaudoin, Swan, Sawyer, and Edison, and a host of others. The first filaments used with any success were made of platinum, but as this fused at a temperature a trifle above white heat, it was exceedingly unreliable. Below white heat it gave insufficient light, and above this point it soon melted. It was evident that some substance was required that could stand considerable variation of temperature without danger of fusion. Carbon possessed this quality, and various vegetable substances, containing a high percentage of carbon, were tried with more or less success—such as silk threads, cotton, jute, sugar, paper, and bamboo. The latter is probably the best natural product for the construction of a filament, and when carbonised and treated properly results in a highly satisfactory and efficient lamp.

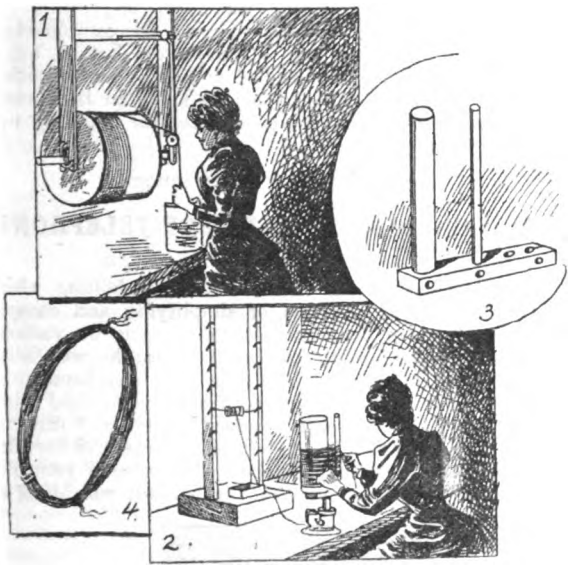

FIG. 1A.—Manufacture of the Filament.—Winding the Filament.—2. Shaping Oval Filament.—3. Spiral Form.—Coil of Filament.

To obtain uniformity of structure and a homogeneous product, manufacturers have experimented with liquid compounds, eliminating air-gaps. The mixtures used are numerous, being the combination of some vegetable fibre with an acid or a salt, as, for instance, the combination of cotton, wood pulp, or silk with sulphuric acid or chloride of zinc. The base and acid are placed in a vessel and thoroughly stirred by means of a rotating spindle provided with paddles until the base is thoroughly mixed. It is next placed in bottles, the liquid being about the consistency of thick molasses, and forced out of the lower ends of the jars through small dies of various sizes, representing the cross-section necessary to make filaments for the different candle-powers and voltages. After the squirting process the fibre is solid, and after being thoroughly washed and purified is wound on drums, shown in Fig. 1A. This is the first step in the operation of drying the filament. Only one layer is reeled on the drum, the drum as it rotates moving horizontally, so that the successive turns cannot fall one on the other. When removed from the drums it is wound on a loose coil, and the two ends of the coil measured with a micrometer. This measurement serves to indicate the particular class of the lamp the fibre is destined for, and consequently which particular form of mandrel it shall be shaped upon.

Another method of attaining the same object consists in using two drums, winding the fibre from one drum to the other. In this case the fibre passes through guides, placed between the drums, which lead the fibre through an acid while in transit.

At the lamp works of the General Electric Company three forms are used for shaping filaments—the oval, for all high-volt low-economy lamps; the spiral, for high-volt 16-c.p. high-economy lamps; and the horseshoe, or loop, for low-volt lamps. The low-volt low candle-power lamps require too short a filament to admit of the use of a spiral or oval. The coil taken from the drum is then wound on the proper form, sometimes called a mandrel, to shape it for the style of lamp desired. The oval and spiral forms are shown in Fig. 1A, the operator being shown in the act of winding the fibre on the oval form, which consists of two vertical rods, the cross-section of one being an ellipse, the other circular. The fibre is wound with one complete turn around the elliptical and half a turn around the cylindrical rod.

The next step in the process of manufacture is the carbonisation of the fibre. A moderately complete description of this process, as carried out by some manufacturers, may be found in Mr. Gilbert S. Ram's work, entitled, "The Incandescent Lamp and its Manufacture." Briefly stated, it amounts to this. The fibre is wound on carbon blocks of the desired shape, but in order to allow for the shrinkage of the fibre, which is very great, the two carbon sections of the form are connected by means of wooden sticks. As the process of carbonisation proceeds the sticks shrink with the fibres, so that at the end of the process the two carbon blocks are in contact. These blocks are packed in a carbon box, about 10 in a box, leaving enough space for the blocks to move freely in the shrinking process. Between each block is a thin partition of carbon, which slides loosely in the box. The carbon box, containing the forms, is then placed in a plumbago crucible, leaving some clearance all round, which is filled up with powdered charcoal. The heat of the furnace into which the crucibles are packed should be very gradually raised, eight hours being about the time required for the first heat (about 600deg. C.). About five or six hours more brings the temperature to a bright red, and an additional three or four hours to a white heat. Whatever the process, we will suppose the fibre carbonised and cut into proper lengths, each length representing a filament as it appears in the finished lamp. Measurements are again taken with a micrometer of each individual filament, which are then sorted out into proper boxes for transfer to the treating-room. If the two ends of the filament do not measure alike, the carbons are rejected. It is to be regretted that there is no space for details, as in a great measure it is the details which would convey to the reader some of the real difficulties of lamp manufacture. For instance, in the handling of the fibre the greatest care must be taken to regulate the shrinkage. A filament squirted with a diameter of 22 mils may after drying be reduced to 10 mils, and again after carbonisation to five mils—a total difference of 17 mils. Now, bearing in mind that with two finished filaments of the same length a difference in cross-section of one mil makes all the difference between a 16-c.p. and a 20-c.p. lamp, some of the trials and tribulations of manufacturers may be understood.

The object of the next process, treating the filament, is, briefly, to give it a uniform and homogeneous surface. Up to this point, no matter what the process adopted and in spite of every care and precaution, the filament is still in a more or less crude state. In all the early filaments the fibrous structure was porous and irregular. The effect of this can be readily conjectured. Each filament consists of an infinite number of small fibres, unsymmetrically arranged, and the electrical current, finding no continuous path, is compelled to jump from fibre to fibre. This forms a succession of infinitely small electric sparks, which (though we may not see them) tend to disintegrate the filament and make a short-lived lamp. The use of a liquid instead of a solid, the quality of the mixture, and, in general, the superior methods of manufacture now employed, render the filament as it now arrives at the treating stage more uniform, and with its porosity and irregularities reduced to a minimum. Nevertheless, it would be far from satisfactory without this treatment. Years ago filaments were manufactured stamped out of paper, carbonised between sheets of paper in moulds, and then

Digitized by Google

treated with a carbon gas. Gasoline vapour has been very usually employed, or any hydrocarbon gas.

The treating apparatus consists, in brief, of two jars provided with tight stoppers, a galvanometer, rheostats, and circuit breaker. Fig. 2 shows an operator holding in her hand the stopper of one of the jars, the necks of which only are visible. The two projections on the stopper are holders for the carbons. The carbons having been placed

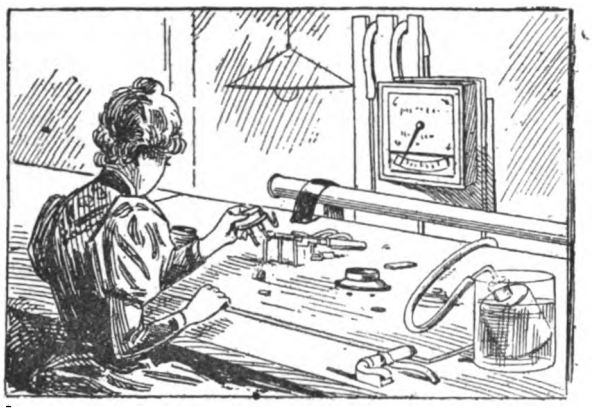

FIG. 2.—Treating Process.

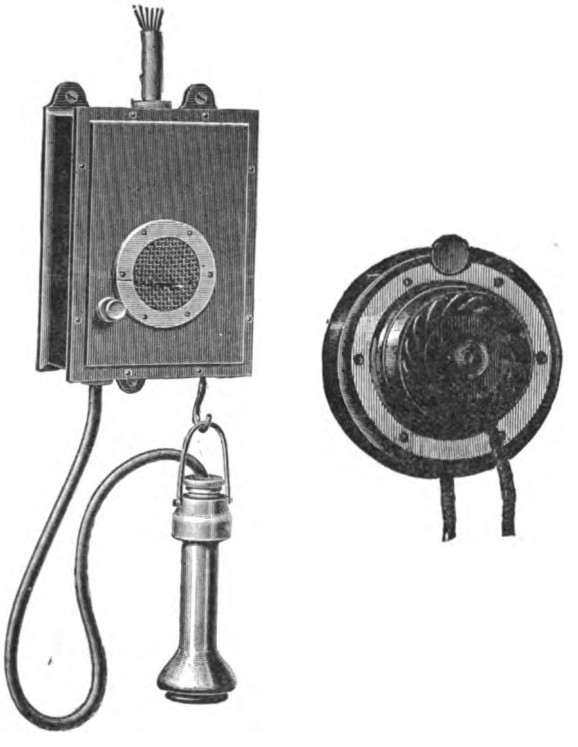
in the holders, the necks of the jars are closed and the circuit is made. The gas in the jar deposits the liberated carbon on the filaments, making a surface of uniform resistance. Since this deposit adds to the surface of the filament it must add to its diameter, causing a considerable reduction in the resistance. The specific resistance of the deposit is also considerably less than that of the filament.

(To be continued.)

MINING AND ENGINE-HOUSE TELEPHONE.

A novelty in the way of telephony has been introduced in the form of a mining and engine-house telephone. This instrument, which has been brought out by the General Electric



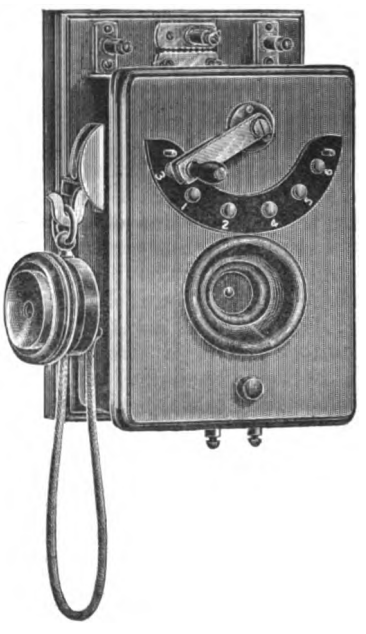
Company, Limited, of 69 and 71, Queen Victoria-street, E.C., has been devised to meet the demand for a good serviceable instrument which will stand a large amount of rough use, and at the same time be practically impervious to injury from moisture, dust, etc. These causes of danger to the proper working of telephones are experienced in mines, engine-houses, engineering works, etc., and the company consider that their mining and engine-house telephone is so constructed as to be unaffected by any of these causes.

The containing case consists of cast iron, with the front screwed on with indiarubber packing, between the sides and front of case. Special precautions have been taken so that no moisture can be admitted through the mouthpiece of the transmitter, or at the point through which the switch-hook enters the case. The receiver is constructed of gunmetal, and is a solid and substantial piece of work, calculated to stand any amount of rough usage without being broken or injured. The flexible cord which connects the receiver with the containing case is protected by a steel flexible tube, which passes through a stuffing-box into the interior of the case at one end, and into the interior of the receiver at the other end. The whole of the movement inside the containing case is mounted on an ebonite slab, so that the working parts are thoroughly insulated from the metal case. The company believe this instrument will be invaluable to colliery proprietors and others who have hitherto been unable to avail themselves of the convenience of a telephone, owing to the difficulty of obtaining an instrument which would stand the wear and tear to which it would be subjected. The "Hunningscone" transmitter "is used, and is a sufficient guarantee that the speaking is both loud and clear, this transmitter still holding its own on the market.

The General Electric Company inform us that they have recently taken over the business of the Anders Telephone Company, and that they are now selling the Anders telephone for domestic purposes under the name of the "Stanley" telephone. This instrument can be readily attached to existing bell wires, and will be found to give great satisfaction. The price is such as places it within the reach of most householders who would have a use for the telephone. The wall-pattern instrument which the company are selling does not exceed 4in. in diameter, and is made in an artistic design, which readily adapts it for being fixed in drawing-rooms, dining-rooms, libraries, etc. The original intention of this combination was that it should supersede the ordinary press button, but it is equally applicable for commercial purposes, being both loud and distinct. The instrument is also made in the form of a small pedestal, which is very convenient for standing upon a desk, table, or mantelshelf.

"RETIRING HOOK" SYSTEM OF TELEPHONES.

The "Retiring Hook" system of telephones, which is another step in the direction of simplifying and cheapening intercommunication between different rooms or stations in large buildings and institutions, such as warehouses, factories, suites of offices, or on private estates, has been brought under our notice. The name is derived from the method adopted, so as to avoid the annoyance caused in other "direct-call" systems by the switches being left as last used, either through carelessness or through the springs which should return them failing to act, and thus preventing another call from being made.



In these instruments the receiver-hook disappears into the instrument as soon as the switch is moved and the receiver taken off, and the operator can therefore not hang up the receiver again until the switch has been put "home." The simplicity of the instrument makes it not only workable, but cheap. The makers, Messrs. Gent and Co., of Leicester, have had considerable success with their intercommunication sets since they took up the sole manufacture of Sloper's instruments, and this adds another to the variety of telephones they manufacture.

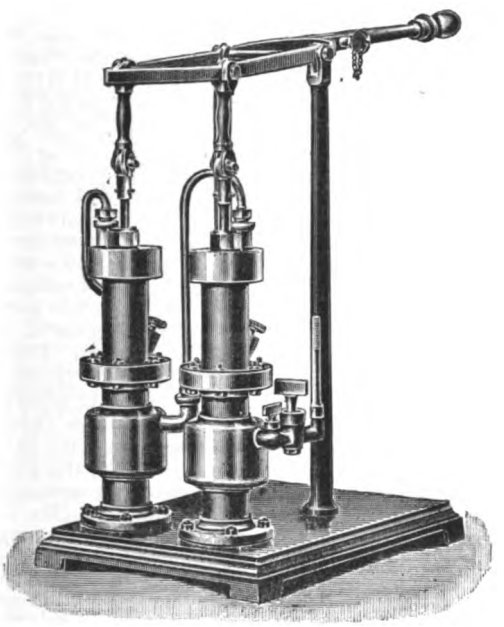
THE GERYK VACUUM PUMP.

It is well known that the tediousness of obtaining a good vacuum has very largely prevented scientific men from investigating the behaviour of various materials *in vacuo*. The difficulties attending the performance of these experiments are the more to be regretted, because, as Prof. Crookes has pointed out, the investigations must prove of value to chemists in the study of several rare cactus and of the many substances which exhibit the property of phosphorescence *in vacuo*. To the electrician the matter is of no less importance whether in the exhaustion of Geissler tubes or of incandescent lamps.

The Geryk pump, here illustrated, whilst giving quick exhaustion, produces a vacuum equal to that obtained by the Sprengel or other mercury pumps. The pump shown in the illustration is a small hand-pump for laboratory use.



The pump may be described as working on the hydraulic principle, but with specially prepared oil practically free from vapour tension. There is no clearance, and it is absolutely positive. This pump has been tested by some of the leading scientists in this country. A small pump, worked by hand, was shown at a recent meeting of the Royal Society and Royal Institution. Geissler tubes were there exhausted in about 70 seconds, which by the ordinary process of exhausting by mercury pumps would have taken an hour. The total stoppage of the spark in the tubes was obtained in a little longer period. These and similar results show that the Geryk pump is capable of doing good work as regards fineness of vacuum. It can be made in any size, and we are informed that the makers, the Pulsometer Engineering Company, Limited, of Nine Elms Ironworks, London, S.W., have supplied them of a capacity of 100 cubic feet per minute. These should prove exceedingly useful to incandescent lamp makers; in fact, the advantage of large pumps producing such a high vacuum can scarcely be over-rated. The makers state that lamps exhausted by these pumps without the aid of mercury pumps are giving first-class results.

PHYSICAL SOCIETY.

At the ordinary meeting on 25th ult., **Mr. Medley** concluded the reading of a paper by Prof. Ayrton and himself on "**Tests of Glow Lamps**," which was commenced at a former meeting. With the newer lamps employed in these tests, it was found that candle-power, current, and candles per watt all rose as the lives of the lamps increased. The authors, being surprised at this result, took care to satisfy themselves that the effect observed was due neither to change in the resistance of their manganin potentiometer strip, nor to uncertainty of contact at the sockets of the lamps. Starting again with new lamps, they found that in all cases the light given out was greater after the lamps had been glowing for some time than it was when they were new. In the earlier tests a considerable falling off in candle-power had always taken place after the lamps had been running for some time Further, while the globes of the earlier lamps were always much blackened, even after a run of a few hundred hours, and so became comparatively useless long before the filament broke, the Edison-Swan lamps now examined showed hardly any blackening, even when the filaments lasted over 1,300 hours. The rise in candle-power was always accompanied by a rise in current, which was, however, proportionally much smaller, so that the consumption of power per candle was actually less after the lamp had been running 50 hours than it was at the beginning. Among the conclusions drawn by the authors were the following: (*a*) when a group of Edison-Swan lamps marked 100-8 are run at 100 volts, and each lamp as its filament breaks is replaced by a new one, it may be expected that the light given out will never subsequently be as small as when all the lamps were new; (*b*) an Edison-Swan lamp marked 100-8 when run at 100 volts will give an average illumination of about 10 candles, and will absorb on an average power of about 4·3 watts per candle, so that such a lamp must be regarded as a 43-watt lamp, and not a 30-watt lamp, as is frequently stated; (*c*) the maximum rise of light recorded during the life of any lamp was 45 per cent.; (*d*) with lamps of the type examined there is no point at which it becomes economical to discard a lamp before its filament actually breaks; (*e*) no marked economy can be gained by over-running such lamps – *i.e.*, by using pressures exceeding 100 volts.

Prof. Ayrton mentioned that the improvement in incandescent lamps after running for some time had been attributed to an improvement in the vacuum. Experiments made on new and used lamps by means of an induction coil showed that the more a lamp was used the better the vacuum became, but he (Prof. Ayrton), though at first inclined to adopt this explanation, had since found that, though in all the lamps examined the progressive improvement of the vacuum was equally marked, the increase in candle-power varied between very wide limits, being very considerable in some lamps and hardly perceptible in others.

Prof Rucker asked if it made any difference to the life of a lamp whether it were kept running continuously until the fibre broke, or were run for periods of a few hours, alternating with intervals of rest? The latter case would more nearly correspond with the conditions obtaining in practice

Prof Ayrton replied that the lamps were kept running during the night and were disconnected during the day.

A paper by **Prof. Anderson** and **Mr. J A. McClelland**, "**On the Temperature of Maximum Density of Water and its Coefficient of Expansion in the Neighbourhood of this Temperature,**" was read by the secretary, Mr. Elder The dilatometer method was used, but the bulb of the instrument contained a quantity of mercury, determined by experiment, which, for the range of temperature concerned, was such as to secure the constancy of the remaining internal volume occupied by water. The observed changes were thus the real and not the apparent changes. The bulb was furnished with a graduated tube of small bore, bent twice at right angles, which served at the same time the purpose of a ground-glass stopper. (The joint was made watertight by a little Canada balsam.) To determine the coefficient of expansion of the glass, the bulb and tube were filled with mercury at 0deg. C. and heated up to about 9° 7 C., the necessary weighings being afterwards performed. The coefficient of expansion of mercury being known, the number of grains of mercury to be kept in the bulb during the experiments on water was calculated. The dilatometer was next filled with (thoroughly boiled) distilled water at about 8deg. C, the stopper end of the graduated tube inserted, and the free end dipped under mercury, giving at 4deg C. a column of mercury whose changes of level could be observed. A thermometer was placed with its bulb close to the middle part of that of the dilatometer, both being immersed in a water bath which could be cooled by the addition of ice cold water or cooled by radiation from surrounding objects. The thermometer used was graduated to tenths of a degree, and was compared with two similarly graduated ones by different makers. The two latter agreed very closely with another, and one had a Kew certificate showing no error in the readings. Temperatures were written to the fourth decimal place, but accuracy to this extent was not claimed. Three sets of experiments were made, and for each a corresponding curve was drawn. In the first the water was at atmospheric pressure; in the other two, at one and a half and two atmospheres respectively. Corresponding to these three pressures the temperatures of maximum density found were 4°·1844 C., 4°·1823, and 4°·1756 The value 4°·1844 corresponding to atmospheric pressure is greater than that generally received.

Mr. Rhodes thought that sufficient precaution had not been taken to accurately calibrate the thermometers. He doubted whether temperatures read in the manner described could be relied upon to much less than 0·1deg. He did not see that any real advantage was gained by having mercury inside the dilatometer to compensate for the expansion of the glass.

Mr. W. Watson thought that the mercury within the vessel would cause further uncertainty by tending to produce distortion of the glass. He pointed out that in the case of water at maximum density there would be practically no convection currents, so that equalisation of temperature would be very slow. As the bulb used was about 8cm. in diameter, and all the experiments were made with the temperature rising, he thought that this would account for the high value obtained for the temperature of maximum density.

Dr. Burton thought a distinct advantage was gained by compensating for the expansion of the glass. The values obtained in different experiments did not seem to be highly concordant.

Prof. Rucker thought that the criticisms which had been passed were for the most part just. For such measurements as those recorded it was not sufficient to know the corrections of the thermometer readings at a few isolated points; the portion of the stem over which the readings were taken must be carefully and minutely calibrated. The Kew certificate not only ignored errors of less than 0·5deg. (as mentioned by the authors), but it only gave corrections for a small number of temperatures separated by considerable intervals.

THE PROJECTED ELECTRIC TRAMWAY AT ACTON.

The Highways Committee of the London County Council presented the following report on Tuesday in regard to the proposed electric tramway to which we have previously referred :

We have considered the application made by the London United Tramways, Limited, which has acquired the undertaking of the West Metropolitan Tramways Company, for the Council's consent, under the latter company's order of 1887, to the use of electricity by means of overhead wires as the motive power for working so much of the tramway in Uxbridge-road, between Shepherd's Bush-green and Acton, as is within the county of London. We have in connection with this matter received deputations from the Vestry of Hammersmith, the road authority of the district, and from the company concerned, in support of the application. The company states that the proposed system is in operation in the most fashionable streets and boulevards in Brussels, Genoa, Florence, Havre, and other important continental cities and towns, and is about to be adopted on some of the tramways at Bristol. The system involves the placing in the centre of the thoroughfares of columns with brackets, with bare copper wires stretched between them; and, having in mind the very decided opinion expressed by the Council some time since against the proposal to adopt the road-centre lamp system for the electric lighting of the Victoria-embankment, the system proposed by the company is, we think, not likely to find favour with the Council. The company urges in support of its proposal that these columns would be of an ornamental character, and could, moreover, be used for the street lanterns ; but we are very doubtful as to the benefit to be derived from such an arrangement. Having regard to the policy which the Council has always adopted with respect to overhead wires, it appears to us most unadvisable that it should consent to the adoption, in any part of London, of a system involving the use of overhead electric wires for working tramways; and it is to be borne in mind that, should the Council consent to the adoption of such a system for tramway purposes, there would probably arise immediately a demand on the part of electric lighting companies to be allowed to place their wires overhead also, especially as no reason can be alleged against the adoption of that course which would not apply with equal force to the tramway wires. We recommend that the consent of the Council be not given to the use by the London United Tramways, Limited, of electricity by means of overhead wires as the motive power for working the West Metropolitan Tramway in that portion of the Uxbridge-road which is within the county of London ; and that the Board of Trade and the London United Tramways, Limited, be informed of this decision.

The committee's recommendation was opposed by Mr. Beachcroft, who proposed as an amendment that the necessary permission should be given. In this he was assisted by the Rev. Fleming Williams. Mr. J. Williams Benn, M.P., and Mr. John Burns, M.P., supported the committee. Ultimately the amendment was rejected, and the committee's recommendation was approved.

THE TRANSFER OF THE TELEGRAPH SYSTEM TO THE STATE.

The twenty-fifth anniversary of the transfer of the telegraphs to the State was commemorated by a dinner, held on Monday in the Whitehall Rooms of the Hôtel Métropole, under the presidency of the Postmaster-General (Mr. Arnold Morley). A card, bearing the dates 1870-1895 and portraits of the 10 Postmasters-General of the quarter of a century, was placed before each guest. Below these were representations of her Majesty's cableship "Monarch" and of a field-service van, and portraits of the late Mr. Patey, Mr. Scudamore, and Mr. Baines. The portraits encircled some statistical information as to the progress of the telegraphs in 25 years. The telegrams—inland, Press, and foreign—have risen from 6,830,000 to 71,465,000, the mileage of line from 14,776 to 32,881, the mileage of wire from 59,430 to 206,304, the instruments in use from 670 to 8,500, the number of words per minute capable of being transmitted on the fastest form of instrument from 70 to 600, and the offices from 2,932 to 9,637 ; and the average charge for ordinary inland telegram has been reduced from 2s. 2d. to 7¾d. The wires were all worked on the simplex plan 25 years ago ; now the processes are simplex, duplex, quadruplex, and sextuplex.

A telegram from Copenhagen was received on Monday by the Postmaster-General from the Great Northern Telegraph Company tendering congratulations on the occasion of the twenty-fifth anniversary of the transfer of the British telegraphs to the State. That company being the only foreign telegraph administration which has enjoyed the privilege of working in connection with the General Post Office on British soil during the whole of that period, they felt called upon to bear testimony not only to the marvellous progress made by the Government telegraph service, but also to express their sincere appreciation of the hospitality and goodwill shown to their company and staff.

The CHAIRMAN, in proposing "The Queen," said that in July, 1837, the first practical working telegraph was constructed by Mr. Wheatstone on the London and North-Western Railway between Euston and Camden Town. In 1851 Great Britain and the Continent were connected by submarine cable, and in 1870 the telegraphs were purchased by the State.

After the toast of "The Prince and Princess of Wales," the Marquis of RIPON proposed "The Military and Civil Services of the Crown." Major-General WEBBER and Sir F. MOWATT responded.

Mr. SHAW LEFEVRE, M.P., proposed "The Telegraph Department." He contrasted the limited facilities for telegraphing that existed 25 years ago with those we now enjoy, and said that the success of the measure of Mr. Ward Hunt for the purchase of the telegraphs was largely due to the energy and ability of Mr. Scudamore. The Government bled freely to the telegraphic companies, but, even at double the real or market value of the telegraphs, the companies were a good riddance. The expenditure of capital and the supposed necessity of paying interest on it weighted the Department and prevented for years the reduction of charges. It was not till 1892 that Mr. Fawcett obtained the consent of the Treasury to the reduction of the charge for a message to 6d., and it fell to his lot, as Mr. Fawcett's successor, to devise a scheme for reducing the minimum charge. In this he was advised by Mr. Patey, one of the most able men in the public service. As to the financial results, a recent return showed that the telegraphs pay their annual cost, but no interest on the capital sum. But the division of expenses between the Post Office branch and the telegraphs branch was of a most artificial character. He had always contended that the two services should be looked at together financially. The net surplus revenue for the two services had been reduced during the last two or three years, owing mainly to great increases of wages, but it was still quite as high as it was in 1884—namely, 2¾ millions—which was a very large contribution to the national resources, the more so when we considered that no other country in the world derived a revenue from its postal and telegraph services. He was confident that in respect of celerity, of accuracy, and of wide extension, there was no telegraph service in the world superior to our own. Under the present able head of the telegraph department (Mr. Lamb), and under its engineer (Mr. Preece), there was security that any advance which an enlightened administration and science could suggest would be adopted, so as to maintain the service at its present high level.

Mr. J. C. LAMB responded, and dwelt upon the benefits which the telegraphs rendered to the country as far exceeding anything which could be presented in financial accounts.

LOANS FOR ELECTRIC LIGHTING.

The Finance Committee of the London County Council reported to that body on Tuesday in regard to certain loans to local authorities for electric lighting purposes. The reports were substantially as follow :

ST. PANCRAS.

We have again had under consideration the application of the Vestry of St. Pancras for a loan of £14,600 for the purposes of electric lighting. We reported on this subject on 17th July last, and recommended, consequent on the Council having granted 42 years to the Vestry of Hampstead for the repayment of a similar loan, that sanction should be given to the Vestry of St. Pancras borrowing £14,300, and that 42 years should be allowed for repayment. On the Treasury being notified that the Council proposed to advance the money to the Vestry, and to spread the repayment over 42 years, exception was taken to that period as being disproportionate to the life of the works. Consequent on such objection, communications took place with the Treasury, and eventually an agreement was come to with the Treasury that the periods for repayment of all loans for the initial cost of electric lighting undertakings should be limited as follows: for land, buildings, culverts, bare copper mains, and royalty licenses relating to such purposes 50 years, and for all other purposes 20 years. This agreement and the letters on the subject were fully set out in our report to the Council on November 20, 1894, when the Council confirmed the agreement as applicable to all future loans for electric lighting, and we have assumed that the Council does not wish to again reopen the question.

Applying these terms to the loans for electric lighting purposes made to St. Pancras Vestry, it is necessary to restrict the period for repayment of this loan (14,300) to 20 years, as the previous loans have been for longer periods. The Vestry of St. Pancras having been so informed, now ask that if the Council will not lend the money for 42 years, it will sanction the Vestry borrowing it elsewhere for that period. The Vestry do not seem to have realised that the agreement referred to above applies not only to loans to be advanced by the Council, but to all loans which the Council sanctions in pursuance of its statutory duty, and that the Council has taken great trouble to obtain the best possible terms for the local authorities in regard to loans for electric lighting

Digitized by Google

purposes. Having carefully considered all the representations made to us by the Vestry of St. Pancras on the subject, we are unable to see our way to suggest any other course than that the Council should adhere to the principle embodied in the agreement with the Treasury, and sanction the borrowing by the Vestry of the sum of £14,300 at 3¼ per cent. for a term not exceeding 20 years. We recommend—

(*a*) That the seal of the Council be affixed to an order sanctioning the borrowing by the Vestry of St. Pancras of the sum of £14,300 towards defraying the cost of electric lighting works at a rate of interest not exceeding £3. 5s. per cent. per annum, such sum being repaid by such equal half-yearly or annual payments as will repay the amount borrowed within a period of 20 years from the date of the loan, and the interest also within the same period. (*b*) That the Vestry of St Pancras be informed that the Council will be prepared, should they desire it, to advance the sum of £14,300 on loan at 3¼ per cent. repayable in 20 years.

A suggestion was made that the period should be 42 years, and after discussion the report was referred back for further consideration.

ISLINGTON.

We have considered an application from the Vestry of Islington for a loan of £51,000 for electric lighting purposes. Of this amount the sum of £18,000 is to be applied towards defraying the cost of erecting a central station at the rear of Eden-grove, Holloway, for which contracts have been entered into for £23,792. 12s. 7d., and the sum of £33,000 is to provide the necessary boilers, engines, dynamos, fittings, switchboards, mains, pipes, and lamps, estimated by the Vestry to cost £34,269, and by the Council's engineer £32,844. The Council has already granted a loan of £9,000 for 55 years to purchase the site. Consequent on the agreement with the Treasury (as to the periods over which loans for the initial cost of electric light installations should be spread), as confirmed by the Council's resolution of November 20, 1894, the Vestry was informed that under that resolution we were prepared to recommend the Council to sanction a loan of £18,000 for 50 years, and £33,000 for 20 years. The Vestry has taken exception to our decision, and contend that the same treatment should be meted out to them as to St Pancras and Hampstead, by granting them 42 years for repayment, and that if the Council itself is not prepared to lend the money for that period, the Council should sanction unconditionally the Vestry borrowing the amount, leaving them to make the best terms they can with some financial corporation as to the rate of interest and the period for repayment, subject only to the restrictions imposed by the Metropolis Management Act of 1855, which provides (Section 190) for the repayment of any moneys borrowed by a sinking fund of not less than 2 per cent. of the amount borrowed, the Vestry regarding this as equivalent to repayment within 50 years.

It is hardly necessary to point out again that the consents in the St. Pancras and Hampstead cases were given before the agreement arrived at with the Treasury, and before the Council's resolution of November 20 last, according to which all loans for electric lighting purposes will for the future be sanctioned. The Vestry of Islington, like St. Pancras, does not seem to appreciate the Council's position in reference to giving its consent to the borrowing of money or to realise the impropriety of the Council consenting to the Vestry borrowing elsewhere for a period of years for which the Council cannot itself properly lend, and thereby rendering nugatory the agreement with the Treasury, a position which we submit it is quite impossible for the Council to adopt. We think that the same course should be adopted in this case as recommended in the case of St. Pancras, and we accordingly recommend—

(*a*) That the seal of the Council be affixed to the order presented herewith whereby the Council sanctions the borrowing by the Vestry of Islington of the sum of £51,000 towards defraying the cost of erecting a station and other works in connection with an electric light installation in the parish, at a rate of interest not exceeding £3. 5s. per cent. per annum, such sum being repaid by such equal half-yearly or annual payments as will repay the amount borrowed, as to £18,000 for the erection of the station within a period of 50 years, and as to £33,000 for plant and works within 20 years from the date of the loan, and the interest also within the same periods. (*b*) That the Vestry of Islington be informed that the Council will be prepared, should they desire it, to advance the sum of £51,000 on loan, at 3¼ per cent., repayable as to £18,000 in 50 years, and £33,000 in 20 years.

This report was also referred back for further consideration.

SHOREDITCH.

We have considered the application from the Vestry of Shoreditch for the loan of £12,200, on the annuity system for 55 years, to purchase a site for a dust destructor and electric lighting station. The Council on July 31 last sanctioned the borrowing of the money for the purposes stated, repayable in 55 years, and the Vestry now ask the Council to make the advance. Owing, however, to the delay in applying for the loan, it is now necessary to require repayment in 54 years. We recommend—

That, subject to all necessary consents and evidence being furnished to the satisfaction of the solicitor of the Council, the application of the Vestry of Shoreditch for a loan of £12 200 to purchase a site for a dust destructor and electric lighting station be granted, on condition that the loan be taken up at once, interest being charged thereon at the rate of £3. 5s. per cent. per annum, calculated quarterly, and, with the principal, being repaid by such equal half-yearly payments of principal and interest combined as will repay the amount borrowed within a period of 54 years; that it be referred to the solicitor to take the necessary measures for completing the loan, and that the amount be advanced out of the consolidated loans fund.

The committee's recommendation was adopted.

LEGAL INTELLIGENCE.

LIVERPOOL OVERHEAD RAILWAY COMPANY v. THE MAYOR AND CORPORATION OF LIVERPOOL.

In the Queen's Bench Division on Tuesday, judgment was delivered by Mr. Justice Wills and Mr. Justice Wright in the case of the Liverpool Overhead Railway Company *v.* the Mayor and Corporation of Liverpool. The question raised by the appeal was whether the Liverpool Overhead Railway, which was leased by the Mersey Docks and Harbour Board to the company, was subject to be assessed to the sewering and paving rates of Liverpool. The appellants had been assessed, and had appealed to the Recorder, and from his decision the present appeal was brought. The appellants contended that the railway formed part of the Mersey Docks and Harbour estates, and as such was exempt from the rates by Act of Parliament. The respondents argued that the railway did not form part of the estate, and did not enjoy the immunity created by the statute.

Mr. Bingham, Q.C., and Mr. W. F. Taylor appeared for the appellants (the Liverpool Overhead Railway), and the respondents were represented by Mr. J. Walton, Q C., and Mr. T. F. Squarey.

Mr. Justice Wills said the foundation of the claim on the part of the overhead railway to be exempt from rating rested on the Liverpool Sanitary Act of 1846, Section 41, and the Liverpool Sanitary Amendment Act, 1854, which provided that the docks, etc., represented by the trustees of the Liverpool docks, should not be ratable in respect to any rates made under these Acts. Subsequently, the said estates, liabilities, and rights of the trustees were transferred to the Mersey Docks and Harbour Board, which was to enjoy all the rights which the trustees of the Liverpool docks then had or enjoyed, or would have had or enjoyed if the Act of 1857 were not passed. It had been assumed upon both sides that the effect of the legislation was that if the overhead railway had been made by the Mersey Docks and Harbour Board, and had been part of their estate, it would have been exempt from liability By an Act of 1888 the appellant company was incorporated, and it was under that Act of Parliament they claimed exemption. An agreement dated April 12, 1888, was entered into by which the appellant company agreed, as lessees, to execute the works authorised by the Acts of 1882 and 1887, and the argument was that a section of the Act of 1888 was applicable to the exemption of the appellant company. His lordship held that the section was intended only to confer upon the lessees whatever powers were to be found contained in the Act which related to the Board generally. Having reviewed the various Acts bearing upon the contention that the railway should be regarded as part of the estate of the Mersey Docks and Harbour Board, his lordship said he had come to the conclusion that the appeal should be dismissed with costs.

Mr. Justice Wright concurred.

COMPANIES' MEETINGS.

ANGLO-AMERICAN TELEGRAPH COMPANY.

The ordinary general half-yearly meeting of the Anglo-American Telegraph Company was held on Friday last at Winchester House, the Marquis of Tweeddale presiding.

The **Chairman**, in moving the adoption of the report and accounts, said that the traffic receipts during the past half-year showed a decrease of £6,948 as compared with the corresponding period of last year. This result was due, of course, to the extreme stagnation which had prevailed in commercial circles for so long a time. The condition of their cables was, on the whole, satisfactory, having regard to their age. The new cable was doing splendid work, and was quite able to carry the whole of their traffic. Their renewal fund amounted to £586,076, and the value of the securities in which it was invested, at the present market value, was £64,903. Since the beginning of the year there had been a substantial increase in their daily receipts, and if the increase continued during the half-year he had no doubt there would be a more favourable report. They proposed a dividend of 14s. per cent. on ordinary stock, making a total distribution for the last year of £2. 2s. per cent., and 28s. per cent. on the preferred stock, making a total distribution for last year of £4. 4s.

Mr. Bevan seconded the adoption of the report, which after some discussion was carried.

EASTERN TELEGRAPH COMPANY.

The half-yearly meeting was held last week at Winchester House, Sir John Pender presiding.

The **Chairman**, in moving the adoption of the report, said there was a decrease of £7,410 in gross revenue realised in the traffic with India, but otherwise there was very little difference between the receipts of the six months under review compared with the

Digitized by Google

corresponding period of 1893. They had carried £4,860 to the maintenance of ships' reserve fund, or an increase of £1,768, as they had done comparatively little work for foreign Governments and for telegraphic companies in the half-year, so that a larger proportion of the depreciation of their ships had to be borne by themselves. There was a decrease of £27,077 in the amount carried forward, but then they had an exceptionally favourable half-year in that which ended September, 1893. However, he was pleased to say that they had recouped the decrease, so far that for the nine months to September 31 they showed a larger total than in the corresponding nine months of 1893, and if the traffic continued as favourable they would be able to show a fair result at the end of their financial year. They had not received the great dividends once expected; but this was owing to the cleverness of their customers, who so used the code that what would have been an enormous traffic was condensed in a few words. Governments showed full confidence in the Company, and he had just been in negotiations which had resulted in their Cape subsidy, which expired five years hence, being renewed for a subsequent 10 years.

The **Marquis of Tweeddale** seconded the adoption of the report, which was agreed to.

DIRECT UNITED STATES CABLE COMPANY.

The thirty-fifth ordinary general meeting was held at Winchester House on Friday last, Sir John Pender presiding.

The **Chairman**, in moving the adoption of the report and accounts for the half-year ended December 31 last, said that their half-year's revenue was some £2,710 less than in the corresponding period of 1893, while the expenses were about £1 300 less. Repairs to a short section of the cable had cost £1,612, debited to reserve fund account, which now amounted to £288,205. Their investment account had been increased by £9,441, and considerable appreciation had taken place in the value of the securities held. There were three powerful combinations for carrying on the work of telegraphing across the Atlantic; in fact, there were more cables than sufficient for the work to be done. As for their own, they were doing all in their power to keep it as thoroughly effective as possible, and at the same time increasing their reserve fund, believing they would be in a better position, with a strong reserve fund, when their cable did give out, than if they had to go to the public for money for a new one.

Mr. C. E. Gunther seconded the motion, which was adopted.

COMPANIES' REPORTS.

YORKSHIRE HOUSE-TO-HOUSE ELECTRICITY COMPANY, LIMITED.

Directors: Grosvenor Talbot, Southfield, Burley, Leeds (chairman); George Henry Crowther, civil engineer, Huddersfield; Robert William Eddison (John Fowler and Co. (Leeds), Limited), engineer, Leeds; Robert Hudson, engineer, Gildersome Foundry, near Leeds; Samuel Ingham (Illingworth, Ingham, and Co.), timber merchant, Leeds; Arthur Greenhow Lupton (William Lupton and Co), cloth manufacturer, Leeds; John Thomas Pearson, The Hall, Melmerby, S.O., Yorkshire. Consulting electrical engineer: Robert Hammond, M.I E.E, Ormond House, Great Trinity-lane, London, E C. Secretary: William T. Green.

Report of the directors to be presented to the ordinary general meeting of the Company to be held at the offices of the Company, Central Electric Lighting Station, Whitehall-road, Leeds, on Tuesday, February 5, 1895, at 2.30 p.m.

The directors submit herewith a statement of the income and expenditure for the past year, and the balance-sheet showing the assets and liabilities of the Company made up to December 31 last. The profit (including £155 6s. 1d. brought forward from the previous year) amounts to £3,671. 12s. 3d., which the directors propose to appropriate as follows:

In writing off the balance of preliminary expenses ...	£1,185	12	2
To set aside as a reserve fund	500	0	0
In payment of a dividend at the rate of 4 per cent. per annum upon the ordinary shares of the Company	1,823	18	4
Leaving to carry forward to next account	162	1	9
	£3,671	12	3

The directors trust that this result of the first full year's operations will be gratifying to the shareholders. The Company's plant (including that put down during the year) has continued to run satisfactorily, and the supply of current is maintained at a high standard of efficiency and regularity. On December 31 last the number of lights connected to the mains was equivalent to 19,858 35-watt lamps; whilst on December 31, 1893, the number was 10,647, showing a large increase for the year. An agreement has been made with the Corporation of the city of Leeds, under which the Company will shortly commence to supply all the electrical energy required in lighting the Leeds Town Hall and municipal buildings, where lamps equivalent to about 6,000 35-watt lamps are installed. The directors have given considerable attention to the question of encouraging the use of electricity for other purposes than lighting, with a view to securing a more constant employment of the Company's plant during daylight hours, and it has been decided to supply current for cooking, heating, and power purposes, at the price of 3d. per Board of Trade unit. As mentioned at the last general meeting, the directors were able to make a favourable agreement with Messrs. John Fowler and Co. (Leeds), Limited, for the exchange of the Company's 100-i.h.p. engine and 50-kilowatt dynamo for plant of four times the capacity, the business having developed so rapidly as to render such an exchange desirable. The new plant is expected to be completed during the coming summer, and the engines then at work will have an aggregate capacity of 1,800 i.h.p. As the extensions decided upon required a small amount more capital than that already provided, the directors arranged with the bankers for a temporary overdraft, secured by a mortgage debenture for £10,000, till the time arrives when a further issue of capital is considered desirable. The retiring directors, Mr. John Thomas Pearson and Mr. Robert William Eddison, being eligible, offer themselves for re-election. Mr. John Gordon, jun., offers himself for re-election as auditor.

LIVERPOOL OVERHEAD RAILWAY COMPANY.

Report of the directors and statement of accounts for the half-year ending December 31, 1894, to be submitted to the thirteenth half-yearly general meeting of the shareholders to be held at the Law Association Rooms, 14, Cook-street, Liverpool, on Tuesday, February 12, 1895, at 3 p.m.

Directors: Sir William Bower Forwood, J.P., Ramleh, Blundellsand; James Barrow, Esq., J.P., 7 Beach-lawn, Waterloo; John Brancker, Esq, J.P., Green Bank, Wavertree; Harold Brocklebank, Esq., 20, Bixteth-street, Liverpool; Richard Hobson, Esq., J.P., 54, Brown's-buildings, Liverpool; Edward Lawrence, Esq, J.P., 5, Fenwick-street, Liverpool; George H. Robertson, Esq., K 35, Exchange-buildings, Liverpool. Engineer and manager: S. B. Cottrell, Esq., A.M.I.C.E, 31, James-street, Liverpool. Secretary: William H. Alexander, Esq., C.A, 24, North John-street, Liverpool.

In presenting the half-yearly statement of capital and revenue accounts to December 31, 1894, the directors have to report that the gross revenue receipts amount to £25,700 19s. 2d., and the working expenses to £17,162. 4s 10d. The number of passengers carried since the opening of the railway being as follows:

	March 6 to June 30, 1893.	Half-year ending Dec. 31, 1893.	Half-year ending June 30, 1894.	Half-year ending Dec. 31, 1894.
First class	235,487	260 221	277 653	362,179
Second class	956,922	1,293,840	1,246 975	2,228,224
Workmen (special return tickets)	178,333	921,578	1,336 809	1,050,976
Total	1,370,742	2 475,639	2,861,437	3,641,379

The increase in the traffic shown by these figures is gratifying to your directors. The increased working expenses are mainly due to the additional train mileage of 70,933 miles due to the opening of the northern extension, and the cost of working the three new stations at the Nelson and Langton Docks and Seaforth Sands. The traffic on the northern extension has fully answered expectations, and the experience which the directors have thus obtained has determined them to ask the shareholders to approve of the construction of the southern extension, for which the Company hold parliamentary powers.

Revenue Account.

Receipts from passenger traffic amount to	£25,336	11	9
Miscellaneous receipts	364	7	5
	£25,700	19	2
Less working expenses	17,162	4	10
	£8,538	14	4
From which deduct—			
Interest on debentures and calls paid in advance	2,520	17	7
	£,6,017	16	9
Add balance brought forward, June 30, 1894	1,248	4	1
Leaving available for dividend	£7,266	0	10

Out of this balance your directors recommend the declaration of dividends at the following rates (less income tax), payable on and after the 16th day of February—viz., 5 per cent. per annum on preference shares. £2,428. 8s. 5d; 2 per cent. per annum on ordinary shares, £3,750—leaving a balance of £1,087. 12s. 5d to be carried forward to next half-year. The directors retiring by rotation at this meeting are Mr. E. Lawrence and Mr. G. H. Robertson, who, being eligible, offer themselves for re-election.

The auditor retiring by rotation is Mr. J. S. Harmood Banner, who is also eligible for re-election.

CITY AND SOUTH LONDON RAILWAY COMPANY.

Directors: Charles Grey Mott, Esq. (chairman), Harrow Weald, Middlesex; Charles Seymour Grenfell, Esq., Elibank, Taplow; Sampson Hanbury, Esq., Wyvenhoe Park, near Colchester; S. Barclay Heward, Esq, 96, Ashley-gardens, Westminster; Edwin Tate Esq., 21, Mincing-lane, London, E C.

Report of the directors, with abstract of accounts for the half-year ending December 31, 1894, to be submitted to the half-yearly ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, E C, to-day at 3 p.m.

The receipts from all sources for the past half-year have amounted to £24,252. 13s. 4d., and the cost of working has been £14,762. 6s. 2d., leaving a profit of £9,490. 7s. 2d. Inclusive of the balance brought forward from June 30 last, the net revenue account shows an aggregate total of £10,919. 8s 10d. After making provision for the debenture and debenture stock interest, a balance remains available for dividend of £6,771. 12s. 10d. Out of this sum your directors recommend that the full dividend of 5 per cent. per annum be paid on the preference shares, and that a dividend at the rate of 1¼ per cent. per annum be paid upon the consolidated ordinary stock, leaving a balance of £950. 7s. 8d. to be carried forward to the next account. The following table shows the number of passengers, exclusive of season-ticket holders, carried since the opening of the railway in each half-year:

Half-year ended	Number of passengers (exclusive of season-ticket holders).	Receipts (including season tickets).
December 31, 1890 (11 days)	165,000	£1,568 3 9
June 30, 1891	2,412,343	19,403 6 9
December 31, 1891	2,749,055	19,798 16 6
June 30, 1892	2,813,162	20,931 4 2
December 31, 1892	3,117,602	22,002 17 5
June 30, 1893	3,146,656	22,458 6 9
December 31, 1893	3,093 351	22,067 14 10
June 30, 1894	3 383 154	23 564 10 6
December 31, 1894	3,275,649	23,540 12 4
Total since the opening of the line	24,155,972	£175,335 13 0

During the past half-year there has been a very satisfactory and steady growth of the traffic during all hours of the day, but especially between 8 a.m. and 10 a.m. in the trains bringing passengers to the City. The trains between these hours have been considerably overcrowded, and as the small accommodation at the King William-street Station prevents any increase in the number of the trains run, a further advance in the fares during those hours has been made. This has had the effect of diminishing the overcrowding of the trains without seriously reducing the receipts. The substitution of motors on the train itself in the place of the present separate locomotives was found to be a more difficult operation than was at first expected, owing to the small size of the tunnels and the sharp curves near the entrance to the King William-street Station. After various experiments, these difficulties have at last been overcome, and a new motor-car train has been satisfactorily completed, and has been approved by the Board of Trade. As this alteration will give an increased carrying capacity to the trains, it is proposed to proceed with the conversion of the existing stock as rapidly as the exigencies of the traffic will allow. By means of these motor trains, there is every reason to expect that the increased traffic which may be anticipated during the present year will be able to be dealt with. But beyond that time there will be no means available for providing for any further increase that may arise, though from the steady growth of the traffic in the past such increase may be confidently expected. Your directors therefore feel that the time has arrived when some steps should be taken to carry into effect the powers granted by the Act of 1893 for the extension to Islington. They would recommend that the line should, in the first instance, be extended to Finsbury-pavement only, the estimated cost of which is £280,000. The first steps to be taken in connection with this operation will be the acquisition of the sites for the stations at the south side of London Bridge, the Bank, and Finsbury-pavement, and as these negotiations are likely to occupy a very considerable time, your directors recommend that they be authorised to proceed with the purchase of these sites at once, leaving the question of time for carrying out the works, and the most advantageous mode of raising the capital, to be discussed at a future meeting. This extension, when completed, would enable more than double the number of trains to be run, and a considerable increase in the accommodation of each train to be provided. The introduction of motor-car trains will necessitate further siding accommodation at Stockwell, which it is proposed to proceed with at an early date. Mr. J. P. Court has given notice of his intention to move at the half-yearly meeting the following resolution: "That the remuneration of the directors be reduced to £650 per annum until the Company pay a dividend at the rate of 2 per cent. per annum upon their ordinary stock." Your directors have always been willing to concur in anything that they believed would further the true interests of the Company; but, viewing the present resolution as practically one of want of confidence in the Board, they trust the shareholders will show by their presence at the meeting or by their proxies their confidence in the present directors. During the past six months £9,100 of the terminable mortgage debenture bonds have been paid off, leaving a balance of £78,000 of the bonds to be dealt with as they fall due. As the powers for the purchase of land under the Clapham Extension Act of 1890 expire this year, it has been necessary to promote a Bill in Parliament for an extension of the times specified in that Act and to sanction the raising of a small amount of additional capital to be expended on the new sidings at Stockwell and for other necessary works. There is also included in the Bill powers to enable the Company to hold its half-yearly meetings in January and July, when the accounts can be prepared and presented to the proprietors at a somewhat earlier date than at present. The Bill will be submitted for your consideration at the special meeting to be held at the conclusion of the half-yearly meeting. The director retiring by rotation is Mr. Charles Grey Mott, who is eligible for re-election.

The auditors retiring are Messrs. Turquand, Youngs, Bishop, and Clarke, who offer themselves for re-election.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Stourbridge.—The Upper Stour Valley Main Sewerage Board call for tenders for cast-iron pipes.

Lathom.—The Urban District Council of Lathom and Burscough require tenders for the supply of cast-iron pipes.

Madrid.—The General Directors of Posts and Telegraphs invite tenders by 19th inst. for 1,000,000 rolls of telegraph paper.

Newport (Mon.).—Tenders are invited for complete electric light installation for the Museum and Art Gallery, Dock-street, in accordance with plans and specifications, which may be seen upon application to Messrs. Swash and Bain, architects, Friars-chambers, Newport.

Hampstead, N.W.—The Vestry of St. John, Hampstead, invite tenders by the 14th inst for the supply of lubricating oil, tools, implements, and other electrical engineers' stores, carbons, and lamps. Further particulars may be obtained of the Surveyor, at the Vestry Hall, Hampstead.

Digitized by Google

Weybridge.—The Urban District Council invite tenders for the public lighting of Weybridge on and after September 29. Tenders should state the number of public lights proposed, the illuminating power, and price per light. Tenders should be sent to Mr. Geo. Wheeler, clerk pro tem. to the Council, before 20th inst.

Manchester.—The Moss Side School Board invite tenders for the installation of the electric light in their schools in Princes-road, Moss Side. Plans, etc., may be obtained from Mr. S V. Clirehugh, A.M.I.C E., Temple-chambers, Brazennose-street, Manchester, on payment of £1. 1s , which will be returned on receipt of *bonâ fide* tender. Tenders are to be sent by Wednesday, February 6, to Mr. W. E. Rowcliffe, clerk to the Board, 30 Cross-street, Manchester.

RESULTS OF TENDERS.

Southampton.—The tender of Messrs. Crompton and Co., at £399. 18s., has been accepted for additional works of electric lighting at the Town Quay, for the Harbour Trustees. Mr. Aldridge was the consulting electrical engineer, and the estimate was £335.

BUSINESS NOTES.

Cardiff.—The new public library buildings are to be lighted by electricity.

Edinburgh.—A proposal is under consideration for the electric lighting of Waverley Market.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,412.

Cowes.—A committee of the District Council is considering the question of introducing the electric light.

Aberdeen.—Trinity Hall buildings are now lighted by electricity, Messrs. New and Mayne having carried out the contract.

Lancaster.—A committee has been appointed by the District Council to examine the plans of the Windermere Electricity Supply Company.

Submarine Cables Trust.—The sum of £1. 5s., balance of the coupon due October 15 last, will be paid by Messrs. Glyn, Mills, and Co. on and after February 1.

Wolverhampton.—A test of the electrical machinery was made last Friday, when the current was turned on to the whole of the arc lamps in the streets. The result was satisfactory.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 27th ult. amounted to £943, as compared with £632 in the corresponding week of last year.

Cuba Submarine Telegraph Company.—The directors recommend a dividend on the ordinary shares at the rate of 8 per cent. per annum, tax free, for the half-year ended December 31.

New Seaham.—The New Seaham Parish Council has been authorised to spend £325 on the lighting of the parish, either by gas or electricity. The Seaham Harbour Gas Company has quoted £3. 5s. per lamp per annum.

Liverpool Overhead Railway Company.—The directors recommend a dividend at the rate of 5 per cent. per annum on the preference, and of 2 per cent. per annum on the ordinary shares, less income tax, carrying forward £1,087.

Medical Electrical Institute.—Mr. Justice Kekewich, on the application on Wednesday, *ex parte*, of Mr. Henderson, for Mr. Furber, a debenture-holder, granted a receiver and manager over Friday next of the Medical Electrical Institute.

Tunbridge Wells.—The erection of the station is proceeding, and the buildings will probably be completed in a few weeks. On Monday the members of the Lighting Committee inspected the main thoroughfares for the purpose of determining the position of the arc lamps.

Llanelly.—It is stated that the Llanelly Gaslight Company have reduced the price of gas from 4s. 2d. to 3s. 10½d. per 1,000ft. Whether the proposal of the Borough Council to light the public buildings and main streets by electricity will come into effect is not yet known.

Moss Side.—Before the Urban District Council Mr. Johnston has complained of the defective lighting in the district, and has moved that it be an instruction to the Lighting Committee to prepare a scheme for the more efficient lighting of the district. The resolution was carried.

Electrical Oil Refining Company, Limited.—This Company has been registered, with a capital of £5,000 in £1 shares, to adopt an agreement and to acquire and develop certain patents relating to the bleaching, refining, sweetening, and purifying of oils and fats by means of electricity.

United Service Institution.—An electric light installation has been provided in this institution. It has been carried out by the General Electric Power and Traction Company, Limited, and Messrs Samuel Cutler and Sons, under the direction of Mr. E. Wingfield Bowles, electrical engineer.

Maidstone.—The Urban District Council having come to no satisfactory arrangement for the transfer of their provisional order, are still open to receive information as to the terms on which a company or firm would undertake and carry out the powers granted by the Maidstone electric lighting order.

Liverpool.—The Mersey Docks and Harbour Board propose to arrange four electric lamps at the entrance to the Alfred Dock, Birkenhead, at an estimated cost of £900. Negotiations are still proceeding with a view to the acquisition by the Corporation of the undertaking of the Liverpool Supply Company.

St. James's and Pall Mall Company.—The directors of the St. James's and Pall Mall Electric Light Company, Limited, recommend a dividend at the rate of 9 per cent. per annum on the ordinary shares for the half-year ending December 31, making with the interim dividend 6½ per cent. for the year.

William Warne and Co., Limited.—This Company has been registered with a capital of £300,000 in £10 shares. The object is to acquire the business of indiarubber manufacturers now carried on by Messrs. G. Coles, G. F. S. Warne, E. H. Coles, O. E. Coles, and J. Burbridge, at 29, Gresham-street, London, and Tottenham.

City and South London Railway.—The receipts of the Company for the week ended January 27 were £998, against £951 for the corresponding week of 1894, or an increase of £47. The total receipts for the current period of the present half-year are £3,999, against £3,839 in the corresponding period of 1894, an increase of £160.

Aberdeen.—Two additional applicants are announced for the post of electrical engineer to the Corporation of Aberdeen, the gentlemen being Mr. Walter H. Tittensor, assistant city electrical engineer, Dundee; and Mr. Wilfred C. Thomson, second resident engineer at the central station of the Westminster Electrical Supply Corporation.

Heanor.—An installation of the electric light has just been inaugurated in the dyeworks of Messrs. I. and R. Morley. The dye-house is 66ft. by 63ft., and in the centre are two 2,000-c.p. arc lights. The electric light has also been fitted up in the offices. The works have been carried out at a cost of £2,000. It is contemplated to instal nine other arc lamps on the premises.

Leeds.—The number of units sold by the Yorkshire House-to-House Electricity Company, Limited, during 1894 was 291,113. Mr. W. T. Green (the secretary) informs us that the respective numbers of 35-watt lights installed at different dates during the year were as follows: January 1, 10,647; March 22, 11,058; June 14, 11,548; September 6, 14,205; and December 31, 19,858.

Hartlepool.—A meeting of the Town Council was held last week to consider the question of the electric trams. Alderman Horsley moved that the notice of the intended application for a provisional order to amend the Hartlepool Tramway Order of 1883, 1884, and 1888, and the draft provisional order relating thereto, having been considered, the Council should approve of the application This was seconded by Councillor Hunter, and carried.

Charing Cross and Strand Company.—The Board of the Charing Cross and Strand Electricity Supply Corporation, Limited, have decided to recommend a dividend at the rate of 5 per cent. for the half-year ending December 31, making, with the interim distribution at the rate of 4 per cent. in August, a distribution for the whole year of 4½ per cent. The balance, of upwards of £2,300, is to be applied to reserve, depreciation, etc.

Tramways Electrical Traction Company, Limited.—This Company has been registered with a capital of £172,500, divided into 15,000 shares of £10 each, and 15,000 shares of £1. 10s. each. The object is to enter into and carry into effect an agreement with the Tramways Company of France, Limited, to acquire concessions, patents, or contracts relating to tramways, omnibuses, or light railways, and to carry on the business of carriers of goods and passengers.

Leominster.—Messrs. Bellow and Son, ironmongers and agricultural implement makers, have recently had their premises electrically lighted. The system of lighting the premises in the occupation of the firm was the work of Messrs. G. Reakes, electrical engineers and contractors, of Shrewsbury. The dynamo is of Messrs. Crompton and Co.'s make and is driven by a 6-h.p. gas-engine. The fittings were supplied by the General Electric Company, of London.

Ramsbottom.—During the past four months operations have been in progress at the works of the Ramsbottom Paper Mill Company, with a view to the lighting of the whole of their buildings by electricity. The installation has now been completed. The contract was held by Messrs. F. H. Royce and Co , of Hulme, The dynamo is capable of supplying current for 400 lamps of 16-c.p. Mr. J. T. Hans, on behalf of Messrs. Royce, has superintended the work.

Robert Sykes and Sons, Limited.—This Company has been registered with a capital of £20,000 in £50 shares. The object is to acquire the business of an ironmonger and iron and steel merchant carried on by Mr. R. Sykes at Stalybridge, Oldham, and Ashton-under Lyne, and to carry on the business of wholesale and retail ironmongers, iron and steel merchants, locksmiths, bell-hangers, gas and hot-water fitters, hydraulic, electrical, and mechanical engineers, etc.

Appointments Vacant.—Messrs. Allen and Co., of Queen's Engineering Works, Bedford, require a foreman in the electrical department to supervise 30 men and boys, winding armatures, magnet coils, etc. Applicants must have a thorough practical knowledge of drum bar and ring armatures, and the fitting and erection of dynamos.—The Yorkshire House-to-House Electricity Company, Limited, Leeds, have an opening for an improver with some electrical training.—The Telegraph Manufacturing Company, of Helsby, near Warrington, require an assistant electrician for the cable department.

Rhondda.—The committee, consisting of a member each of the five wards of the Rhondda Urban District Council, specially appointed to formulate a scheme to light the whole of the valleys by electricity, held its first meeting recently at the Public Offices, Pentre, to consider the replies received from the various colliery

Digitized by Google

companies in the district respecting the matter. The proceedings were private, but the communications from the collieries are said to be favourable to the proposed scheme. The Rhondda District Council is now determined to light certain large sections of the valleys if not the whole, by electricity.

Hackney, N.E.—The question of the electric lighting of the parish came up for discussion at the last meeting of the Vestry. It was stated that the provisional order which was obtained some time ago would expire next June; that unless the Vestry took immediate steps the powers would most likely be taken out of their hands; that a local company would then step in and would undertake a supply. After several members had deprecated the latter course, it was decided to take up the question, and as some of the old committee had failed to get re-elected, or had resigned office, a new committee was appointed to make enquiries and forward this matter.

Prospect Steam-Pump.—Messrs. Cole, Marchent, and Co, of Bradford, have sent us a copy of their catalogue of a new and improved duplex steam-pump which they are putting on the market. The firm believe that this pump is the only direct-acting pump in the market which can be made to work and use steam expansively, consequently there is a saving of steam by its use. The expansion is capable of variation. In addition to this advantage, the firm claim to be able to pump a greater quantity of water than any other pump of the same size. If for electric light stations, the economy of steam obtained by this pump will be of advantage without in any way adding to the complication of the installation.

Ventilating Appliances.—An action was brought last week in the City of London Court by Messrs. Joel and Co. against Messrs. Matthews and Yates. It was brought by the plaintiffs, electrical engineers, to recover the sum of £25. 18s. 6d. against the defendants, of Swinton, near Manchester. Mr. Gray was counsel for the plaintiffs, and Mr. Arnold White for the defendants. The claim was for putting up certain ventilating apparatus at The Mecca, Cheapside, and the Champion Hotel, Aldersgate-street. The defence was that the plaintiffs had been paid all that was due to them, and that they were not entitled to recover any portion of the amount claimed. The defendants also contended that if the motors which were fixed were not satisfactory, they were to be removed, but that was denied. The jury found for the plaintiffs for £17. 15s. 7d.

Claim for Injuries—The record has been closed in an action in Aberdeen Sheriff Court at the instance of Mrs. Georgina Hogg against the Town Council, claiming £100 for damages. The plaintiff states that on July 10, 1893, the defendants were engaged laying along Castle-street electric wires for the purpose of giving a public supply of electric light in Aberdeen. On that date she had occasion to go to the New Market, and in passing along Castle-street fell into a part of the excavations, where she lay stunned until she was lifted out by some people who chanced to be passing. She avers that she was seriously bruised and injured, particularly on the left side and the left side of the head, and confined to bed for a fortnight. The Town Council admit that on that date their contractors, Messrs. Scott and Sellar, were engaged in laying electric wires in Castle-street, but deny that operations were being carried on at the part where the plaintiff says the accident took place.

Bath.—The clerk mentioned, in reply to a question at a meeting of the Surveying Committee of the Town Council last week, that he had forwarded the communication of the authority to the Board of Trade with reference to the electric lighting and the opposition of the authority to the application of the company. He also stated that he had received acknowledgements from the Board of Trade and also from the agents. At the same meeting Alderman Sturges mentioned that the quarterly bill of the electric light company had given him considerable trouble owing to the failures of the light. They were all very much obliged to the company for keeping their lights in when the gaslight was out, and therefore they ought to have some respect paid to them. At a previous meeting Mr. Knight moved a resolution with which he quite sympathised, that they should not be fined for any failure occasioned by the flood. There were several items in dispute, and he moved that they pay the company £521, the bill being £553, and leave the Lighting Committee to deal with the difference.

Carnforth.—The Lancaster District Council last week had before them the renewed application of the Windermere Electric Lighting Company for the consent of the Council to lay mains for the supply of current within their district. At a previous meeting consent had been refused on the ground that the company proposed to supply only part of the district, which would leave half of Carnforth without the electric current, and also because some members looked upon the power the company would have as a monopoly. Mr. W. Dodd, J.P., Silverdale, said he did not think any other company would be able to supply current with such advantage to the community. He understood their terms would be 3d. per unit, equal to 1s. 6d. per 1,000ft. of gas. Mr. E. B. Dawson, J.P., Aldcliffe Hall, said his only objection was that they proposed to supply only part of their district. It was quite certain that if they could utilise the water power of Lake Windermere with success, no other company would be able to compete with them. The clerk was instructed to ascertain on what terms the company proposed to supply the district, and Messrs. Dodd, Dawson, and Knowles were appointed to examine the plans and report at the next meeting.

Belfast.—The municipal central station, to which we referred in our last issue, was set in operation on Wednesday of last week. The ceremony of turning on the electric light was performed by the Lord Mayor (Mr. Wm. M'Cammond, J.P.) and Alderman W. J. Pirrie, J.P., chairman of the Electric Lighting Committee of the Corporation, in the presence of several of that committee and other members of the Corporation. Sir Samuel Black, town clerk, was also present, as were Prof. Kennedy and Mr. M'Cowen, electrical engineer to the Corporation. That evening 2,000 lamps were supplied to about 40 subscribers in the principal thoroughfares of the city. Immediately after the light was switched on, the Lord Mayor, Alderman Pirrie, and the other members of the Electric Lighting Committee and Corporation proceeded to the Theatre Royal for the purpose of satisfying themselves as to the character of the light supplied. The installation there has been carried out by Messrs. Richard Patterson and Co., of High-street. Besides Messrs. Patterson, the contractors who have carried out the wiring of other establishments were Mr. C. C. M'Carthy, William-street South; Mr. George Combe, High-street; Messrs. W. H. Drennan and Co, Fountain-street; Messrs. William Coates and Sons, Fountain-street; Messrs. T. Verity and Sons, Messrs. Cooney and Swan, Mr J. H. Greenhill, Messrs. Gent and Co., Mr. J. Hind, jun., Victoria-chambers, and Messrs. Allen and Sons.

Great Northern and City Railway.—The Great Northern and City Railway Company, incorporated by Act of Parliament with a share capital of £1,500,000 in £10 shares, announces the issue of £1,000,000, the application list for which will close on or before Monday. The line will be about three miles long, and will be connected with and afford direct through communication between Finsbury Park, where the various suburban lines of the Great Northern Railway Company converge, and Moorgate-street, in the City of London, and will provide a frequent service for the densely-populated districts through which it passes. The motive power will be electricity, but the railway will differ from other electric railways in that the tunnels will be of main-line size, and will take the Great Northern's heaviest suburban trains. The estimated cost of the whole undertaking is £1,400,000, the contractor constructing and equipping the line for a fixed maximum sum. The Great Northern Company, besides constructing at its own cost so much of the railway as lies north of Drayton Park, also guarantees, in connection with through traffic only, minimum payments and rentals, together amounting to about £30,000 per annum, for one-fourth of the train service and other accommodation. This sum is equivalent to £2 per cent. per annum upon the whole share capital. The annual income from local traffic is estimated at £90,000, and the working expenses, exclusive of the Great Northern contribution, at £50,000.

Fareham.—A resolution was passed last week at a meeting of the Fareham Urban District Council asking the Local Government Board to withhold consent to the borrowing of £7 000 for the purchase of the undertaking of the Fareham Electric Lighting Company, Limited, on the ground that the ratepayers were opposed to the said purchase as evidenced by the recent election. After Mr. Sandy had given notice of his intention to move the resolution in question, a letter was received from the Local Government Board stating that the effect of communications addressed to that body, and the consideration of evidence taken at the recent enquiry conducted by Colonel Marsh, led to the conclusion that it was doubtful whether the proposed purchase met with the approval of the general body of ratepayers of the district, and having regard to the fact that the Fareham Urban Council had come into office since the application for sanction to the loan was submitted, the Board had decided to defer dealing with that application until informed whether the Council desired to proceed with the matter. It was agreed that the letter should be brought forward for consideration at the February meeting of the Council, and Mr. Smith gave notice of a motion that in the interests of the ratepayers it was desirable that the Council should make the following offer to the electric lighting company—viz, to pay to the company an additional sum of £150 per annum for lighting the town until the termination of the company's existing contract in September, 1896, subject to the terms and conditions set forth in the managing director's circular of June 1, such payment to commence from March 1 next, and in other respects the terms and conditions of the existing contract to remain in force conditionally upon the withdrawal by the company of the *quasi*-contract for the sale and purchase, and that the clerk be instructed to make the offer at once.

Ealing.—The Electric Lighting Committee reported to the Urban District Council last week that an application had been received from Mr. Landor, photographer, asking when the electric light would be available all day. The surveyor informed the Council that a day supply of the current was not practicable at present; there was not sufficient demand to warrant the provision of such a supply. The committee further reported that 64 applications, involving 4,033 lamps, had been received for private installations of the electric light; 54 of these requested installations, with a total of 3,375 lamps, had been made. Sixty-three of the street arc lamps had been erected, and the electric lighting of the Uxbridge-road had been finished from the Acton boundary to the Culmington-road at Ealing Dean; the centre road lamps from the latter point to the Hanwell boundary, the erection of which would complete the street-lighting of the district, would it was expected shortly be put up. The extension of the mains to The Avenue at Castle-hill, for private lighting purposes, was being proceeded with. The committee further reported that they were of opinion that the time had arrived when Messrs. Bramwell and Harris, the engineers employed under the electric lighting scheme, should make some definite report concerning the whole of the electric light installation and the completion of the work. The committee recommended that Messrs Bramwell and Harris should be asked to make this

Digitized by Google

report accordingly. The recommendation was adopted by the Council, as was also a recommendation by the Finance Committee that Messrs. Bramwell and Harris should be requested to furnish a statement of accounts with reference to the electric lighting showing the amount of work already done and the further sum estimated to be required, and also distinguishing the extra works in respect of which special instructions had been given by the Local Board.

Signal Recorder for Ships.—Messrs. J. Davis and Son, of Derby and London, are introducing the Thompson and Marsden recorder, which is a simple one, and records indelibly every order signalled to the engine-room from the bridge, and also the exact hour and minute at which every order was signalled. Under the present system no record exists of the orders that are given, and in a large majority of cases of collision or accident the only evidence before the court is the statement of the master on the one hand, and the engineer on the other, which evidence is frequently very conflicting both as to the orders given and also as to the time elapsing between orders. It is obvious that these are matters of the utmost importance in arriving at a decision as to whom is to blame. The instrument now invented in no way interferes with the action of the indicators already in use, but is merely an accessory and a silent and accurate witness and recorder of every movement of the indicator. The recorder consists of a drum which revolves once in 12 hours, the motive power being supplied by a powerful English eight-day clock. Around the drum a chart is placed which is renewed at 8 a.m. for the day watch, and at 8 p.m. for the night watch. The chart contains a column of all the words of command printed within horizontal lines which run the whole length of the chart; vertical lines divide and subdivide the chart into hours, quarters, and single minutes, and as the space allotted to each minute measures one-eighth of an inch, the eye can easily subdivide this into smaller fractions of time. A metallic pencil rests upon the chart, and by simple mechanism is connected with the existing indicators in such a manner that the recording pencil is moved up and down by the action of the indicator, thus producing vertical lines on the chart, and the completion of the diagram is brought about by the revolution of the drum. The effect of the recorder is threefold: (1) long vertical lines show the precise moment at which the signal-bell rang; (2) angles show the time at which each order was given and what that order was; (3) horizontal lines show how long each order remained in force without alteration. There is no question as to whether the recorder will do the work the inventors claim for it, as it has already been subjected to a long and severe test by a well-known steamship company with complete success. Several high authorities on nautical matters have expressed their opinion that the want of such an instrument has been long felt, and no doubt before long a recorder will be considered a necessary equipment of all steam vessels.

Lambeth, S.E.—An animated discussion took place at a meeting of the Vestry last week on the question of electric lighting in the parish. The question arose upon the report of the clerk (Mr. H. J. Smith) as to the position of the parish in regard to the electric lighting order. He explained that in 1892 powers were given to the Vestry to light the whole of the parish except the two areas comprised in the orders granted to the London Electric Supply Corporation and the Installation and Maintenance Company. The order granted to the Vestry provided that they should, within a period of two years after June 27, 1892, lay down and maintain sufficient distributing mains for the purposes of general supply of electricity throughout all the streets in which tramway lines are laid down (except Milkwood-road), with the addition of Effra-road, Tulse-hill, Denmark-hill, Herne-hill, and Knight's Hill-road. The order further required the Vestry to lay down at any time after the expiration of 18 months from June 27, 1892, sufficient distributing mains for general supply throughout every other street within the area covered by the order within six months after being required to do so in the manner provided by the order. The Vestry had not up to this time taken any steps under the order or done anything to carry out its provisions, and the order was liable to be revoked at any time by the Board of Trade. Should any company apply this year for an order the Board of Trade would hardly pay much attention to any opposition of the Vestry if they, having an order, declined or neglected to put its powers into force. Mr. Hubbard moved that the report be referred to a special committee for consideration and report. Mr. Everett seconded. Mr. Hooper said he failed to see why the matter should be referred to a committee, seeing that it had already been fully considered. He believed there were a large number of members of the Vestry opposed to the expenditure of a large sum of money upon electric lighting. He moved, as an amendment, that the Board of Trade be asked to extend the time under the order. The amendment having been seconded, Mr. Hubbard, in replying to the discussion, complained that many speakers had done an injustice to Mr. Preece in not quoting the full context of his report. As to Mr. Howlett's speech, it was the most thorough monopolist utterance he had ever heard. But why did not Mr. Howlett and others who thought with him face the plain issue—whether they should abandon the order or not. Well, that was the logical conclusion of Mr. Howlett's attitude. He (Mr. Hubbard) did not ask them to enter upon a speculation, but simply to appoint a couple of dozen men, rather than 120, to give them information. Then they could have some concrete resolutions to accept or reject. Mr. Hooper eventually withdrew his amendment, and a proposition by Mr. Ogilvie to hold a special meeting in three weeks' time to consider the question was, on a division, adopted. Mr. Williams gave notice that at the special meeting he should move that the provisional order should be surrendered.

Leeds Tramways.—In the course of an article on the subject, the *Yorkshire Post* of Tuesday's date says the Tramways Committee has for many months past been enquiring into and obtaining information of the various systems of tramway traction in use in the country, with a view of guiding the Highways Committee to a conclusion as to the system that would be most likely to suit the requirements of Leeds; and for several weeks the information so gained has been in process of being boiled down into a concise and readable report. The document came for the first time before the committee a week ago. As the question is one of interest to every burgess of Leeds, it might have been thought that the committee, having at last produced its report, would at once take the Highways Committee, the Corporation, and the ratepayers into their confidence by publishing it. Instead of doing this, however, precautions were taken to keep the contents of the report secret. Again, at an adjourned meeting of the committee (Alderman Firth presiding), held on Monday, greater precautions were taken to keep secret what was no longer a secret—the committee sitting with guarded doors. The more important portions of the report have leaked out, the parts withheld being the grounds on which two special systems of traction found favour. It was stated on Saturday that the decision of the committee would lie between cable traction and electric traction, and as far as the report was concerned the consideration of those two methods occupied Monday's meeting entirely. Addressing themselves to the subject-matter of the report, and mainly to that portion of it which relates to the system of traction to be selected, the members of the committee spent about an hour in comparing the respective merits of the electric and the cable methods, which seem to the city engineer, Mr. Hewson, and the committee, to be the only two feasible systems. In the course of the debate the meeting was informed that the cost of working cars by means of electric overhead wires, including equipments, is about £10,000 a mile per annum, that if electric wires are laid underground the outlay will be about £14,000 a mile, that the cable system would involve an outlay of about £12,000 per mile a year, and that about 25 miles of tramway are now being worked by the Corporation. Eventually the committee declared itself in favour of electricity as the motive power of the future, and proceeded to consider the difference in the cost of overhead and underground wires. A strong desire was expressed to the effect that in all the main central thoroughfares the electric wires should be underground, if that arrangement would not militate against successful working. A majority of Alderman Firth's colleagues did not seem to mind the extra £4,000 a mile for electric wires in conduits provided the smooth and punctual running of the cars could be ensured. Ultimately the city engineer was asked to furnish the committee with all the information at his command as to the extra cost which would be incurred by the laying of the electric wires in conduits in the heart of the city. Mr. Hewson was also asked to afford the committee all the additional information he can as to the relative advantages and disadvantages, particularly with reference to cost, of the overhead and underground electric systems. The meeting was adjourned for a week to allow the engineer time to prepare the further details required. When the Leeds Tramways Committee first addressed itself about a year ago to the question of what system of haulage they should adopt, two or three proposals were brought before them; but later on, when they advertised for tenders for working the lines, the only tender received was from Mr. W. S. Graff Baker, who instituted the Roundhay electric tramways. Mr. Graff-Baker's tender was sent in on behalf of a company with which he is associated, and the terms were as follows: for a lease of the tramway lines in Leeds for a period of 21 years, with a right to use a conduit or underground electric service in the centre of the city and an overhead wire electric service outside such centre, he offered, subject to the conditions governing the tenders, the sum of £615 per mile of single line per annum by way of rental. Including the Roundhay and Harehills road and Beckett-street tramways, the total length of single line within the city is, in round numbers, about 28 miles; and for the use of this Mr. Graff-Baker offered £17,220 per annum. To the acceptance of this offer at the time it was received and discussed many of the members of the committee were favourable; but as they had begun their enquiries into the several systems of traction in use in this country and on the Continent, they resolved to proceed until they had exhausted the question. The offer still holds good, and the generally favourable impression produced by it originally has not been removed by subsequent enquiries.

PROVISIONAL PATENTS, 1895.

JANUARY 21.

1385. **Improvements in galvanic batteries.** Henry Tipping, 55, Chancery-lane, London.

1405. **Improvements in electric arc lamps.** Louis Barrière, 46, Lincoln's-inn-fields, London.

JANUARY 22.

1436. **Improvements in and relating to pillars or posts for electric lighting, carrying electric wires, railway signals, and the like.** John Bell Millar, of the firm of George Smith and Co., Sun Foundry, Limited, 96, Buchanan-street, Glasgow.

Digitized by Google

1442. **Improvements in electrical ceiling roses.** Charles Leigh Clarke and William Paul Theermann, 7, South parade, Manchester.

1446. **Improvements in galvanic batteries.** Charles Bernhardt Schoenmehl and Clark Murray Platt, 70, Wellington-street, Glasgow. (Complete specification.)

1474. **Electromagnetic brakes.** John Hopkinson, 5, Victoria-street, Westminster.

1477. **Improvements in feeding mechanism for electric arc lamps.** Henry Bevis and Gustav Binswanger, 73, St. Stephen's-road, Upton Park, London.

1478. **An improved insulated support for electrical conductors.** Hugo Hirst, 73, St. Stephen's-road, Upton Park, London.

1504. **Improvements in coin-controlled apparatus for producing various electrical phenomena or effects.** William Phillips Thompson, 6, Lord-street, Liverpool. (Joseph L. Ketcher, United States.) (Complete specification.)

1512. **Improvements in electric arc lamps.** Sir Charles Henry Augustus Frederick Lockhart Ross, Bart., 6, Bream's-buildings, Chancery-lane, London.

1526. **Underground conduit for electric roads.** Ezra Aley Mather, 40, Chancery-lane, London. (Complete specification.)

1536. **Improvements in or in connection with alternating-current electric motors.** Brown, Boveri, and Co., 46, Lincoln's-inn-fields, London. (Date applied for under Patents, etc., Act, 1883, Section 103, July 3, 1894, being date of application in Switzerland.)

1544. **Improvements in and relating to electrical conductors.** Edward Dudley Lewis, 77, Chancery-lane, London. (Complete specification.)

JANUARY 23.

1546. **An electric switch.** Frank Wright and Edward Jesse Piper, 34, Victoria-street, Westminster. (Complete specification.)

1550. **Improvements in electrical switches.** Charles Leigh Clarke and William Paul Theermann, 7, South-parade, Manchester.

1558. **Improvements in ceiling roses and other similar electric fittings.** John Glynn Williams and Henry Mostyn Darrah, 70, Market-street, Manchester.

1587. **Improvements in or appertaining to electrical clocks, bells, indicators, and similar instruments.** Frank Hope-Jones and George Bennett Bowell, 31, High Holborn, London.

1611. **Improvements in and connected with the electric lighting and heating and also the ventilation of railway carriages and other vehicles.** Edwin James Preston, of the firm of J. Stone and Co., and Arthur Bernard Gill, 77, Chancery-lane, London.

JANUARY 24.

1649. **Gas-engines, ignition by electricity.** Henry Crane, jun., 182, Moseley-street, Birmingham.

1676. **Improvements in electrical storage batteries.** Thomas Ballard Marchant and John Woolley, 42, Manby-grove, Stratford, London.

1697. **Improvements in and connected with arc lamps.** Hermann Niewerth and Regina Niewerth, 37, Cursitor-street, Chancery-lane, London.

1698. **Improvements in electric current regulators.** Hermann Niewerth and Regina Niewerth, 37, Cursitor street, Chancery-lane, London.

1707. **Electric water-gas.** John Henrique Dunn and John Parsons, 272, Holloway-road, London.

1710. **Safety fixing for the various decoration covers and lamp-holders for electric light fittings.** Francis James Curley, 49, Flood street, Chelsea, London.

1714. **An improvement in electrical glow lamps.** Siemens Bros. and Co, Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.)

1717. **Improvements in and relating to electric accumulators.** Oscar Pirsch, 45, Southampton-buildings, Chancery-lane, London.

1730. **Improvements in electrical devices for lighting cigars, or for other like purposes.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

1731. **Improvements in secondary batteries.** Camille Alphonse Faure and Frank King, 47, Lincoln's-inn-fields, London.

JANUARY 25.

1744. **Improvements in microphones or telephone transmitters** Clarence Metcalfe Stead and Lawrence Walter Douthwaite, trading as the Electrical Mechanical Agency Company, 2, East-parade, Leeds.

1788. **Improvements in apparatus for the manufacture electrolytically of tubes and other articles of circular section.** Francis Edward Elmore, 28, Southampton-buildings, Chancery-lane, London.

1797. **Improvements in filaments and carbons for electric lamps.** Peter Stiens, 24, Southampton-buildings, Chancery-lane, London.

JANUARY 26.

1824. **Improvements in wattmeters.** John Perry, 31, Brunswick square, London.

1835. **Improvements in electric exploders.** Herbert Vivian Keeson, 40, Loudoun-road, St. John's Wood, London.

1840. **An improved carbon transmitter or microphone.** Guillaume Arnaud Nussbaum, 29, Ludgate-hill, London.

1854. **Improvements in electric burglar alarms for doors.** Gerald Rickett Blackburn, 2, Market-street, Bradford.

1867. **Improvements in shade-holders for electric, gas, or other lights.** William Everett Gibson and Hugo Hirst, 73, St. Stephen's road, Upton Park, London.

1885. **Improvements in insulating devices or attachments for electric wires.** Augustus Henry Weikman, 6, Lord-street, Liverpool.

1899. **Improvements in connection with electric railways or tramways.** Edgar Mapple, 47, Lincoln's-inn-fields, London.

1906. **Improvements in electric condensers.** George Threlfall, 46, Lincoln's-inn-fields, London. (Richard Threlfall, Australia.)

NOTES.

Society of Arts.—On Wednesday next, at 8 p.m., a paper on "Light Railways," by Mr. W. M. Acworth, will be read.

South Africa.—The Matabeleland telegraph is now open to Gwelo, which is regarded as a very promising mining centre.

Liquid Fuel.—Experiments are about to be made with liquid fuel on one of the river firefloats of the London County Council.

Electric Carriage.—An electric carriage, equipped with Fulmen secondary batteries, is now to be seen in operation in Paris.

Electric Railways.—The *Financial Times* of Saturday last devoted a long leading article to this subject, which it looks upon with favour.

Light Railways.—The Queen's Speech promises that a proposal will be presented to Parliament for facilitating the construction of light railways.

First Aid.—Mr. W. S. Hedley, M.D. (Edin.), again discusses in the *Lancet* the question of first aid in the case of accidents caused through electric shocks.

A Novelty.—The *Echo*, on Wednesday, discovered the existence of something in connection with electric light mains which it describes as "a heavy volt cover."

Unique Switches.—A revised price-list of the various types of "Unique" switches made by Mr. A. P. Lundberg, of Bradbury-street, Kingsland, N., London, has been issued.

Good for the Trade.—A dispute between two actresses engaged in a Sheffield pantomime resulted, a few days ago, in the smashing of the lamps in the electric ballet.

Sanction of Loan.—The Treasury have sanctioned the loan by the London County Council of £12,200 for the erection of a dust destructor and electric lighting station by the Shoreditch Vestry.

Institution of Civil Engineers.—On Tuesday next, at 8 p.m., a discussion will take place upon the paper, by Mr. John Richardson, on "The Mechanical and Electrical Regulation of Steam-engines."

A Good Library.—The German Minister of Finance has bought the library of the late Prof. von Helmholtz for the Physikalisch-Technische Reichsanstalt. The professor was the head of this institution for many years.

Electric Light in France.—In accordance with the resolution taken last November, tenders are now being invited for the electric lighting of the Chamber of Deputies. Only French firms will, however, be allowed to tender.

The Brooklyn Strike.—The United States militiamen, according to a sketch in the New York *Electrical Review* illustrating the strike of tramway employés in Brooklyn, very much resemble many of the French soldiers.

Institution of Electrical Engineers.—A paper on "Reversible Regenerative Armatures and Short Air-Space Dynamos," by Mr. W. B. Sayers, associate, will be read at a meeting of this Institution on Thursday next, the 14th inst.

Personal.—Mr. E. O. Walker, who was formerly connected with the Indian Government Telegraph Department, has been appointed to succeed Mr. Simpson as superintendent of telegraphs and electrician in the island of Ceylon.

London and Epping Forest Railway.—Mr. Campion, examiner on Standing Orders, decided on Tuesday that the Standing Orders had been complied with in the case of the London, Walthamstow, and Epping Forest Railway Bill.

Thomson-Houston Regulator Patent.—Judge Grosscup has dismissed the bill of the Thomson-Houston Electric Company against the Western Electric Company for alleged infringement of the Thomson-Houston dynamo regulator patent of 1881.

Correction.—The two feed pumps mentioned last week in our description of the Wolverhampton electricity works as being of the Cameron duplex type, should have been stated to have been of the single-ram vertical type, made by Mr. Jos. Evans, of Wolverhampton.

Northern Society of Electrical Engineers.—A paper by Mr. G. S. Corlett, member of council, on "Electricity as Applied to Mines," will be read before this society at a meeting to be held on Monday next at the Palatine Hotel, Hunt's Bank, Manchester.

The History.—An esteemed contemporary, which a few weeks ago did not like our giving historical sketches of the steps leading up to the adoption of the electric light by municipal authorities, has now followed our example. That is always the worst of setting a bad example.

Use of Electric Motors.—A pamphlet bearing the title of "The Application of Electromotors for Power Purposes" has been issued, at the price of 1s., by Mr. T. L. Miller, A.M.I.C.E., M.I.E.E., of 7, Tower-buildings, N. Water-street, Liverpool. The pamphlet deals with various cases where electric motors have been introduced, and points out their advantages.

Storage Battery Traction.—The *Zeitschrift für Elektrotechnik* of the 1st inst. contains nearly 20 pages relating to the employment of the Waddel-Entz accumulators for traction purposes in Vienna. It will be remembered that the experiments about to be commenced are to be watched by a technical commission, who will furnish a report on the subject.

Lecture.—A lecture, entitled "Electricity in Mining," was delivered on Wednesday of last week by Mr. G. R. Peers, A.I.E.E., before the mining class in connection with the Walkden Technical Instruction Committee. Some experiments were performed during the evening, including electric shot-firing, which system is coming into general use in the collieries of the district.

Chicago Edison Company.—Some 20 pages of the New York *Electrical Engineer* of the 23rd ult. are devoted to an illustrated description of the history and work of the Chicago Edison Company. It appears that no less than 40 per cent. of the total output of the company is utilised for driving motors, by no means confined to the fan or smaller sizes, but running up to 50 h.p. or 60 h.p., and in one case even to 110 h.p.

Long-Distance Telephony.—A Vienna correspondent telegraphs that the Austrian Government has accepted a proposal made by Italy for a telephone line to be constructed between Vienna and Milan. The line will be ready in the course of this year. Telephone communication between Milan and Rome is already existing, and the line connecting the Austrian and Italian capitals will be, it is stated, the longest in Europe.

Central Stations in France.—*L'Industrie Electrique*, of Paris, publishes, in its issue of January 25, its fifth edition of statistics of central stations in France, the figures being brought up to January 1, 1895. The number of stations in existence or in progress in France amounts to 440. These figures, however, include installations which supply only a couple of consumers. The

Digitized by Google

figures for Algiers are 11; for Réunion, 1; and for Senegal, 1.

State Telephony.—Judging from a circular recently issued by the French Postal Administration, State telephony there is in a peculiar position. The amount voted for telephony when the Government took over the telephone system in 1889 has only been paid in half, and that has been expended, and the Department has now been compelled to decline to accept further subscribers to the system. This exemplifies, a French contemporary says, the beauties of the working of the telephone service by the State.

Refuse Destructors.—The *Surveyor* in its last issue prints as an editorial comment, but without acknowledgement, some of the remarks made by Mr. F. H. Medhurst to a *Pall Mall* young man on the subject of refuse destructors. Like the young man in question, as mentioned in our last issue, the *Surveyor* seems to be ignorant of the fact that Mr. Charles Jones, the surveyor to the Ealing District Council, was the first to carry into practice the use of refuse destructors for steam-raising purposes in connection with electric lighting from a central station.

Institution of Engineers and Shipbuilders.—The fifth general meeting of the present session will be held in the lecture hall of the Literary and Philosophical Society of Newcastle-upon-Tyne, on Tuesday next, at 7.30 p.m. The business will include the reply of Mr. F. Caws to the discussion on his paper on "Ship Acceleration and Fluid Resistance"; discussion on Mr. W. C. Mountain's paper on "The Design and Efficiency of Plant for the Transmission of Power by Electricity"; and a paper on "The Application of the Electric Arc to Machinery, Boiler Repairs, etc.," by Mr. Henry Foster, will be read.

Fire Alarm.—The Geneva Society of Arts have had brought under their attention by Mr. J. Bulet an alarm for giving warning of a rise in temperature in any room. The apparatus, as lucidedly described by a French contemporary, is formed of a metal stem, the dilation of which causes a contact to be made and an electric bell to ring. This alarm is regulated for the normal temperature of the room, and any increase in the temperature due to an abnormal condition is immediately made known. The sensitiveness of the alarm is such, our contemporary concludes, that a match or a piece of paper held underneath it will cause the bell to ring. The sensitiveness of the alarm seems to be such that most people would prefer to dispense with it, on the ground of over-sensitiveness.

Compressed Air v. Electric Traction.—A note in our business columns last week referred to the registration of the Tramways Electric Traction Company, the object of which, we are informed, is to construct electric tramways in Rouen. Since that announcement appeared, we gather from a French contemporary, which quotes from a Rouen paper, that the Société Générale d'Eclairage et de Force Motrice, of Paris, which work the Popp system for lighting and the Conti compressed-air system for tramways, have also approached the municipal authorities of Rouen with a view to a concession being granted for the construction and working of tramways in that town on the Conti system. The Conti system, it will be remembered, was described in our issue of April 20, 1894.

Electric Power in Engineering Works.—In our issue of October 19 we reproduced the presidential address delivered by Mr. T. Richardson before the North-East Coast Institution of Engineers and Shipbuilders. The current issue of the *Transactions* of this institution contains the address and the discussion thereon. In addition to this, photographs are given in illustration of the address. One is of a large straightening machine driven by a 3½-h.p. electric motor at the works of Messrs. Dorman, Long, and Co., Middlesbrough. The second shows a double punching machine actuated at the same works by a 6-h.p. motor. In the third photo is represented a Pieper multipolar flywheel dynamo of 500 h.p., coupled to a compound-condensing Corliss engine, at the National Arms Factory, Herstal, Belgium, whilst the fourth illustrates a row of electric motors driving lines of shafts at the same factory.

Institution of Junior Engineers.—The fourth meeting of this session will be held at the Westminster Palace Hotel, Victoria-street, on Friday evening, 15th inst. Mr. H. J. Young will occupy the chair. The paper to be read and discussed is "The Practical Application of Alternating-Current Motors," by Mr. Walter J. Fryer, A.I.E.E., member. The following is the synopsis: Theoretical aspect of alternating-current system of supply in England—Difficulties of working single-phase motors; frequency, dead points, etc.—Description of Brown and Oerlikon motors; winding and connection of coils—Application of motors to organ-blowing plant; requirements to be fulfilled, advantages of electric motors for the work to be performed, automatic clutch pulleys, reduction gear, self-starting arrangements, object of condenser and resistances, methods of switching. Several motors will be exhibited, lent by the General Electric Company, and will possibly be working.

Electrical Communication with Lighthouses.—This subject was referred to on Monday, by the Earl of Morley, at the annual meeting of the Plymouth Chamber of Commerce. His lordship stated that for the first time they saw that some really useful work had been done in that direction. They might try to persuade the Government to expend the £200,000 necessary for the completion of the work, but he was afraid they would be told by the Treasury that they had other pressing claims on their resources, and that they would have some difficulty in providing so large a sum of money. The matter, however, was a very important one, and he trusted that the Treasury and the Board of Trade might put their heads together and bring about a more rapid development of the telegraphic system between the shore and the lightships and lighthouses. The experience at Eddystone last year, when the "Dunottar Castle" went aground, was, no doubt, a remarkable one, but it brought vividly before them the dangers which great ships ran on account of the rocks around our shores, and the great value which immediate communication with the shore would be in saving life.

"D.P." Storage Batteries.—A few weeks ago we described the new type of "D.P." cell brought out by Messrs. Johnson and Phillips, of London and Charlton, for the electrical illumination of railway trains. Since then the firm have issued a new illustrated price-list of the "D.P." storage batteries, of which they have supplied during the past few years cells which if placed in a continuous line would reach a distance of six miles. It will be remembered that these accumulators, which are arranged either in glass or wooden boxes, combine the durability of the Planté cell with the capacity of the pasted form. The plates afford a large working area and the cells can be charged and discharged at high rates without the bringing about of any disintegration or buckling. Messrs. Johnson and Phillips now pay carriage on these accumulators to any part of Great Britain, this being equivalent to a great reduction in price. Durability being the predominant feature of the battery, this word will in future always be associated with it. The discharge rates of the cells are now nearly 20 per cent. better than formerly, whilst the renewal rates are common to the "D.P." or

Digitized by Google

pasted form of cells—*e.g.*, the firm renew either their own or other makers' cells at the same rate.

London County Council and Traction.—Writing to the *Pall Mall Gazette* from the National Liberal Club, Mr. Joseph Nelson says: "I went to witness the proceedings of the London County Council upon the application of a tramway company for permission to introduce the electric system of traction for about one mile within the jurisdiction of the London County Council. After listening to the speeches against the innovation, I said to myself, Am I living in the year 1835, when I began my first railway survey? For through all the intervening period I have never listened to such senseless objections as those which were uttered. My experience extends to the evidence before thousands of committees of the Lords and Commons; but, above all, the most violent and unfounded statements were those made by Mr. John Burns. If he is a sample of the Progressives of the County Council, I shall not be surprised if that section meets with a severe reverse in the coming election. I have no interest whatever in the company that applied for the permission, but I have a deep interest in seeing the perfect success of the tramway system in the United Kingdom, of which I was one of the first authors."

Transmission of Power at the Sheba Mines.—An interesting example of the electrical transmission of power is being carried out by Messrs. Johnson and Phillips, of London and Charlton, at the Sheba gold mines, 10 miles distant from Barberton, South Africa. This installation is described in an illustrated pamphlet issued by the firm. Hitherto the ore has been conveyed to the stamps, a distance of three miles, by means of an aerial tramway, but the development of the mines has been so great that the directors of the Sheba Gold Mining Company decided early last year to lay down additional stamps not on the site of the then existing stamps, but at the mine itself, and to transmit the power for working them by means of electricity. The electrical energy is transmitted through five miles of underground cable, curving round the hills from the Queen's River. The available water power is estimated at 600 h.p., and two 300-h.p. turbines have been laid down for driving the generators. The power-house, which has been built on a slope by the Queen's River, contains two alternators, and the current is transmitted to the receiving-house at the mine. Here the pressure is reduced by means of transformers, and the electrical energy is conveyed by other cables to different points for the operation of motors working the stamps, pumps, settlers, breakers, etc. In a future issue we hope to refer again to this important installation.

Society of Engineers.—The president for 1894 (Mr. G. A. Goodwin), who occupied the chair at the opening of the first meeting of the present session at the Westminster Palace Hotel on Monday evening, presented the premiums awarded for papers read during that year—namely, the president's gold medal to Mr. T. W. Baker for his paper on the "Utilisation of Town Refuse for Generating Steam"; the Bessemer premium to Mr. E. C. de Segundo for his paper on "Power Distribution by Electricity, Water, and Gas"; the Rawlinson premium to Mr. R. Nelson Boyd for his paper on "A Deep Boring near Friestadt, Austria, by the Canadian System"; and a society's premium to Mr. H. B. Ransom for his paper on "The Principles and Practice of Hydro-Extraction." Mr. Goodwin introduced the new president (Mr. W. G. Peirce) to the meeting, and retired from the chair. The new president, in his address, referred to the progress of electric traction as shown by the City and South London Railway and the Liverpool overhead line, the successful working of which, he said, had paved the way for the Waterloo and City electric line, of which he gave particulars. As for the explosions which had occurred in underground systems, he thought there could be little doubt that in most instances they were caused by a leakage of coal gas, fired by a spark from the electric cables, which had for some reason or other become short-circuited.

Electric Traction in Germany.—The Minister of the Interior has approved of an electric tramway being laid from Leipzic to the suburbs of Mockau, Schönefeld, and Grosseschocher.—The owner of Hafkrug, a Baltic watering place, proposes to connect a new hotel which is now being built with Glesehendorf railway station by means of an electric tramway.—A committee of the Berlin Municipality which visited Deutz to examine the Langen overhead suspended railway system, recommend that a concession should be granted for one of the lines which Mr. Langen is desirous of building. They report that what they saw at the works impressed them favourably.—The local authorities of Reichenberg have granted a concession to Messrs. Schuckert and Co., of Nuremberg, for an electric tramway there.—At Bochum the Municipality have decided to build an electric tramway from the Bergisch-Märkisch railway station to the starting point of the Herne electric tramway, which was opened a few weeks ago. The work will be entrusted to Messrs. Siemens and Halske. Electric traction has been introduced on the horse tramway line between Rathhausmarkt and Einsbüttel, Hamburg.—The Munich local authorities have approved of electric traction being adopted on the Färbergraben-Isarthalbahnhof tramway line.—An arrangement has been come to between representatives of the Municipality and the Hanover tramway company whereby accumulator traction is to be introduced on all the lines of the company within a period of five years.

Electric Hot-Plates for Restaurants.—We are glad to learn that electrical hot-plates are now being supplied to hotels, restaurants, etc., for keeping food warm when supplied to the customers. Messrs. Crompton and Co., the makers, state that one restaurant in the West-end is now proposing to adopt the system of supplying an electric hot-plate to each customer on which to stand dishes containing the food. With the usual system the plate gets gradually colder and colder, and the latter part of the course is seldom so satisfactory as the first; but the electric hot-plate rectifies this defect. Some restaurant proprietors who do not see their way to supply the hot-plate free to their customers propose making a charge of 1d. for its use. It is found that a circular hot-plate 8in. in diameter may be maintained at a temperature of 212deg. at an expenditure of one ampere at 100 volts. This would cost less than ½d. per hour. There appears to be considerable scope in this direction, and the durability of the plates should be very great, as they are not strained in reaching the above-mentioned comparatively low temperature. Another system is sometimes adopted—that of using a quick-heating plate which is connected when the order is given. The plate becomes hot in a couple of minutes, and is then used in the same manner as a hot-water plate. In the latter case no connecting wires are required on the table, the plate being previously heated from some convenient spot. It is found that the plates retain their heat for a considerable time.

Electricity in the Production of Wine.—In *L'Electricien* of the 2nd inst. is given an illustrated description of a combined electric light and power plant in use at the wine-producing establishment of MM. Pech and Baudoin at Abziza, Algeria. The idea of putting down the installation arose from the fact that it was found that electrical plant

Digitized by Google

would be the most serviceable for placing under the control of the Arabs employed in the establishment. The generating plant comprises a compound dynamo and a steam-engine, the current from the former being utilised for lighting purposes and for actuating seven electric motors of powers ranging from two to ten effective horse-power. One of the motors drives a one-ton crane, which is used for lifting boxes of grapes from the ground floor to the beating-room; three motors operate the beaters and presses, and the remaining three are coupled direct to centrifugal pumps, which circulate the must in the tuns. The work of the electric motors, and consequently the load on the generating dynamo, is extremely variable. It might therefore be expected that variations in the speed of the steam-engine and also in the luminosity of the lamps would take place. This difficulty has, however, been overcome by using a compound dynamo and by the perfect regulation of the steam-engine. In the case of the pumps driven by electric motors, it may be mentioned that each set is arranged on a small trolley running on a narrow-gauge line, the current being conveyed to the motor by a flexible cable. The installation, which was carried out by Messrs. Sautter, Harlé, and Co., was supervised by M. Baudoin.

Decimal Weights and Measures.—Various resolutions will be submitted at the forthcoming annual meeting of the Association of Chambers of Commerce to be held on March 12, 13, and 14. One, a London proposal, is to the effect that the association learns with satisfaction of the willingness of her Majesty's Government to appoint a select committee for the purpose of ascertaining whether any, and if so what, changes have now become necessary in the British system of weights and measures, and in order to give full effect to the repeatedly and unanimously expressed opinion of this association in favour of the adoption of the metric system of weights and measures, the executive council be requested (*a*) to collect evidence from members of the association with a view of placing the reasons for the desired reform forcibly before the intended committee; and (*b*) to secure the introduction of a Bill for the amendment of the Weights and Measures Acts with the object of removing doubts as to the legality of traders engaged in export business possessing and using metric weights and measures for export trade purposes, provision for the verification and stamping of which—on comparison with the Board of Trade metric standards—is already made in those Acts for the purposes of science and manufacture. A second resolution, emanating from Leeds, suggests that, having regard to the repeated demands of the commercial community for the adoption of a decimal system of weights and measures in place of the present complicated and irregular system, which is found to hamper trade and retard education, and having regard also to the practically unanimous desire expressed in favour of the metric system now in use in most foreign countries, the executive be urged to take immediate steps to bring about the change, and, if considered advisable, to secure the introduction of a Bill into Parliament during the next session providing for the permissive use of the metric system for two years, after which time it shall become compulsory.

Pacific Cable Question.—The Inter-Colonial Postal Congress, which met at Hobart on Friday and Saturday last, discussed, among other matters, the question of the Pacific cable. Mr. Thynne moved a resolution in favour of the construction, working, and maintenance of a cable, through British territory and under British control, from Vancouver to Australia, to be undertaken by the Governments of Great Britain, Canada, and Australasia, and the cost to be borne equally by the three countries. The route proposed was from Vancouver by Neckar Island to Fiji, and thence to Caloundra, in Queensland. If Neckar Island could not be placed under British control, the route would be by Fanning Island instead of Neckar Island. The motion further advised that a commission of the three countries should be appointed to conduct the financial arrangements, and that the Government of Canada should be requested to continue their good offices in promoting the undertaking. Mr. Cook moved an amendment reaffirming the desirability of a Pacific cable, and urging the Governments to take steps in the matter. The amendment was carried. In regard to the cable guarantee, Mr. Ward moved that Victoria should reconsider its withdrawal. The conference went into committee to confer on this point. As the result of the consultation, Mr. Ward moved before the conference that the colonies should agree to guarantee an international revenue to the Eastern Extension Telegraph Company up to £227,000 per annum, making up any loss below that amount, provided it did not exceed £10,000; also to guarantee a revenue from the New Zealand cable of £20,000, making up the loss if it did not exceed £9,000, provided the rates were not higher than at present; the agreement to be from year to year and terminable on two months' notice. The arrangement is to be referred to Sir John Pender for approval. The conference has since resolved that the committee should further consider the cable guarantees and Sir John Pender's reply regarding the proposal made by the conference in the resolution of Saturday.

Effects of Strong Electric Currents. — M. Bernhardt, in the *Centralblatt für die Medicinischen Wissenschaften*, has collected several instances of death by electricity. In one recorded by Dr. J. Kratter, as quoted by the *Lancet*, a man aged 26 was traversed by a current of high tension—1,600 to 2,000 volts—and was found breathing stertorously a few steps from the point where he made contact. Death soon took place. The post-mortem examination, after the lapse of 21 hours from the time of death, disclosed two small wounds—one on the left index finger, and the other on the back—and there were large extravasations of blood in their vicinity. All the organs of the body showed hypervenous blood, acute œdema of the lungs was present, and there were extravasations into the sheath common to the cartodid and vagus, along all the vertebræ, into the intercostal spaces, around the œsophagus, beneath the peritoneum and elsewhere. The muscles of the body were in an extreme condition of rigor mortis. The heart was partially relaxed. No macroscopic changes could be seen in any part of the nervous system. Kratter thinks that the electrical shock suddenly paralysed the heart, which was the immediate cause of death, accompanied by œdema of the lungs, causing hypervenosity of the blood. There was a marked contusion on the left side of the diaphragm at the point of contact of the heart. Experiments made on animals showed that in them the respiration was usually primarily arrested, which caused asphyxia and secondary stoppage of the heart's action, though sometimes the heart was first affected. In a second case, reported by M. D'Arsonval, a man was struck with a current of 4,500 volts (the ampere-meter indicated 750 milliamperes). The current entered at his hand and issued at his back. Half-an-hour or more elapsed before any attempts at resuscitation were made, but on artificial respiration being practised on Silvester's method recovery took place. Lastly, Dr. Donnellan reports a case of the passage of a current of 1,000 volts through a man, which instantly caused coma, dilated pupils, pallor of the face, and sweating; delirium, and tonic alternating with clonic spasms, followed. The pulse was 80. The

Digitized by Google

respiration, at first stertorous, passed into the Cheyne-Stokes type. After the injection, first of morphia and then of strychnia, the patient fell into a deep sleep, from which he awoke convalescent.

Electric Light v. Gas.—A correspondent writes to the *Colliery Guardian* as follows: "If the electric light supersedes gas for illuminating purposes, the manufacturers of gas cannot ascribe any of the blame to the high cost of their raw materials, for, as a matter of fact, their expenses of production are much below their receipts; so much so that there is scarcely a gas company in the country which does not pay to its shareholders a heavy dividend, whether general trade is depressed or not. Ten per cent. is a very common dividend declared by gas companies even in such times as the present, and we hear of them, in addition to this, turning over large amounts to reserve funds, whereas those who supply them with materials, particularly coal, have to be content with little or no dividend, and yet the gas companies press for lower prices of coal, though they are obtaining the fuel now for less money than was ever before known. As a rule, amongst themselves there is no competition; each company has its own field, with no one to dispute its monopoly, and so the price of their gas can be kept up, but among the coalowners the case is very different, and competition being very keen, the prices are cut down to extremely low figures, greatly to the benefit of the gas companies. In Durham, however, some thirty-four of the owners of the leading gas-coal collieries have formed a syndicate to resist the persistent pressure put upon them by the gas corporations, and it would be well if their brethren of other districts would follow the example. By their greed for big dividends the gas companies are hastening the time when their light will be superseded by something better, and they are stimulating inventors to devise cheap and efficient substitutes. Thus they are playing into the hands of their rivals, and must eventually ruin their trade, and with it the coal trade must severely suffer, because so much coal is now raised solely for gasmaking purposes. Probably the gas companies are working for the present only, foreseeing that the electric light is the light of the future, and that if they want profits they must secure them now and let the future take care of itself."

Telegraphy in East Africa.—Some misunderstanding appears to have prevailed in colonial circles in Berlin, as to the negotiations which were carried on between Germany and England on the subject of Mr. Rhodes's proposed line of telegraph. A *Times* correspondent states that the course of the negotiation was as follows: The British Government sounded the German Government as to whether it would be willing to grant facilities for the laying of a line of telegraph through German East Africa. The German authorities treated this question, it is admitted, in a dilatory manner, and finally returned an evasive answer—not from any illwill towards England, but from a natural anxiety as to the possible consequences of the execution of Mr. Rhodes's scheme if their assent were given. As, they argued, the line would pass through a wild part of their territory, it would be absolutely necessary for Mr. Rhodes to erect stations for its defence, which in the long run might have to protect the wire by force of arms. This consideration appeared to the German Government to be sufficiently weighty to justify a reserved attitude. While matters were still at this stage, the German Government was approached on the subject from another side. A delegate of the South-West Africa Company entered into negotiations with the colonial authorities, and proposed that if the Imperial Government could not consent to the original suggestion for the laying of a line of telegraph through its territory, to be under English management, it would, perhaps, not object to the formation of a German company which should be floated with English capital and should control the telegraph on German soil. For this purpose, however, Germany was requested to grant concessions of land on both sides of the wire. To this plan, again, Germany could not consent. The correspondent has the best grounds for believing that these statements, so far as they go, are correct. It will be seen that those circles in which it was asserted that Mr. Rhodes had demanded fortified stations were evidently of opinion that the objections raised by the German Government referred to a definite request. Further, Mr. Rhodes was not personally concerned in the negotiations, though it was assumed that the delegate of the South-West Africa Company was acting in his interests. That this gentleman emphasised the necessity of concessions of land on both sides of the line of telegraph is firmly maintained.

Rapid Transit in New York.—A report by Mr. Parsons has been presented to the New York Rapid Transit Commission on some of the engineering features and cost of the proposed electric railway under Broadway. The principal difficulties lie in the part of the line below Fourteenth-street. Here the rock lies at a considerable depth, and over it are beds of unstable sands. The great buildings which line Broadway and the sidewalk vaults, which would have to be cut into in case a four-track road near the surface were installed, complicate the problem greatly. The construction of a four-track line as shown on the plans without disturbing the surface of the street, involves tunnelling methods that are without precedent. The success of such methods is entirely problematical, and the great risks to all the interests involved do not justify their consideration. The only practical method by which such a road can be constructed would be by open cut, although the objections as to requiring underpinning of the abutting buildings and the invasion of property right would still remain. Mr. Parsons suggests, instead of building under Broadway below Fourteenth-street, a four-track railway from Union-square through New Elm-street to the City Hall, and thence a two-track line through Nassau and Broad streets to the South Ferry. This could be supplemented at any time, if desired, by a two-track line from Union-square through University-place, Greene and Church streets to the City Hall. Since the express trains would make no stops between Fourteenth-street and the City Hall, a two-track line on Church-street would give the same accommodation between those points to the territory west of Broadway that the four tracks do to that east of Broadway. If, however, the committee desires to adhere to the Broadway route, he suggests the treatment of the local tracks and the express tracks as separate railways and the construction of each independent of the other, so as to obtain the maximum of efficiency for both. The former would naturally follow the undulations of the street as closely as possible in order to have a minimum depth at the station platforms, while the express line should have shallow stations at long distances, and between these stations be run on more favourable gradients. By the plans submitted, the railway would be constructed by taking one-half at a time, laying the side walls in a trench and then turning half the arch. The other half of the tunnel would be completed later. All the material beneath this arch could be excavated after the latter was completed and the street surface restored. The lower tunnel could be constructed by means of circular shields, and as these would be driven beneath the masonry tunnel previously constructed, there would be little danger of a movement of the ground sufficient to affect the street surface.

Digitized by Google

THE PREVENTION OF EXPLOSIONS IN CONNECTION WITH UNDERGROUND MAINS.

Will those gentlemen who have not already replied to our questions on this subject kindly send in their answers as early as possible? The following have been received during the week:

Aberdare.

The two lines published under this heading in our last issue referred, not to Aberdare, but to the Ogmore Valley station.

Scarborough.

Mr. GERARD S. PECK, of the Scarborough Electric Supply Company, Limited, reports that no trouble has been found through the accumulations of gas. The company have a special engine driving a blower, which forces a current of air through the pipes. This method has been quite satisfactory. The mains are made watertight, and any water could be removed at the boxes; but after 17 months' running very little trouble has arisen.

Whitehaven.

Mr. J. W. BRODIE, the engineer of the Whitehaven Corporation electricity works, has experienced no trouble in connection with accumulations of gas. No necessity has arisen for providing against the possibility of explosions. He regards good ventilation of the surface covers as the most practical method of overcoming explosions. The culverts are drained into the sewers and trapped. No trouble has been caused by electrolysis.

Major-General C. E. Webber

has not experienced any difficulty in regard to explosions of gas. The difficulty has been overcome by constructing the culverts in such a manner that gas cannot leak into them except through the negligence of the persons in charge. This method has been successful. When practicable, General Webber ventilates the street boxes and transformer-chambers, but he states that it is not always practicable to do so. With regard to the prevention of explosions, he observes that explosions cannot take place in a conduit, in pipes, or cable-ways when one cable is drawn in and the space round the cable where it enters a box caulked with spun tarred yarn. From the earliest days he has always advocated that each conductor should have a separate way. If these conditions are existent, explosions within a conduit, pipe, or way is practically impossible. Concerning drainage, he states that draining should not have to be thought of in a well-laid conduit, pipe, or way, but in practice he always has them laid with a fall each or either way to the nearest box. Spare "ways" should always be plugged up at each end. General Webber has not the least hesitation in stating that if the precautions described in his paper on the City of London electric lighting in February, 1894, are complied with, there is no risk to that system, in which each conductor has a separate way.

THE NEW-MAYNE ELECTRIC RUDDER MOTOR.

A new type of electric motor suitable for small pleasure boats has been recently brought out by Messrs. New and Mayne, electrical engineers, of Palace-chambers, Bridge-street, Westminster, and of Woking.

The makers had long thought that it would be a great advantage to all owners of pleasure boats if they could obtain a type of electric motor which could be easily adapted to any ordinary rowing-boat, without the necessity for structural alterations. One of the great obstacles to the extended use of the ordinary types of motor arises from the fact that either an entirely new boat must be ordered, specially fitted with electric apparatus, or such expensive alterations are needed in the case of the ordinary rowing-boat as to dissuade many persons from undertaking the work. The makers considered that if some type of motor could be so built and enclosed in a suitable case as to act both as motor and rudder that it could then be attached to the boat by the ordinary fixtures used for the rudder, and could thus be easily shipped and unshipped. The chief difficulty met with was in the design of the motor, which must necessarily be very light and compact.

The final type arrived at is illustrated in Figs. 1 and 2, in which Fig. 1 is a side elevation, and Fig. 2 a plan of the whole apparatus ready to be put upon the stern of the boat.

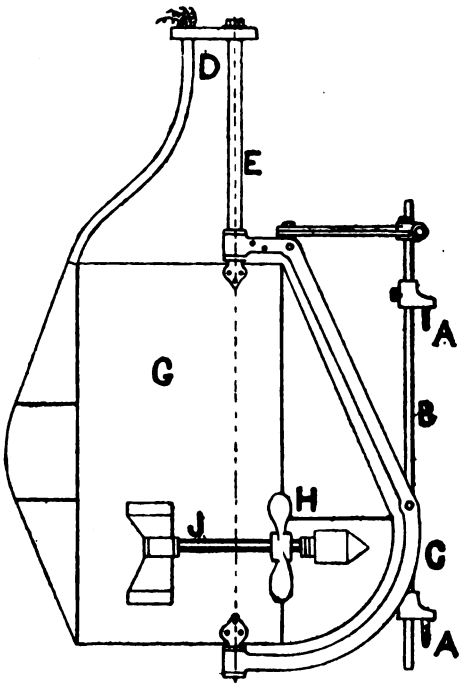

FIG. 1.

The particular size illustrated is adapted for a double sculler, which is the type of boat most commonly used on the Thames. The whole weight of the apparatus is carried by the two eyebolts on the stern of the boat which serve to support the ordinary rudder. The spindle, *b*, carries two adjustable pins, *a a*, which can be moved so as to suit any boat. The double-bent frame, *c*, is provided top and bottom with bearings, in which the top bar, *e*, and the bottom pin, *f*, can swing round. The motor itself is enclosed in a watertight brass case, *g*, which is provided at the end with separate covers, so that the brushes can be examined. The armature shaft is provided with a bevel wheel which gears into a similar bevel wheel keyed upon a vertical spindle inside the case near

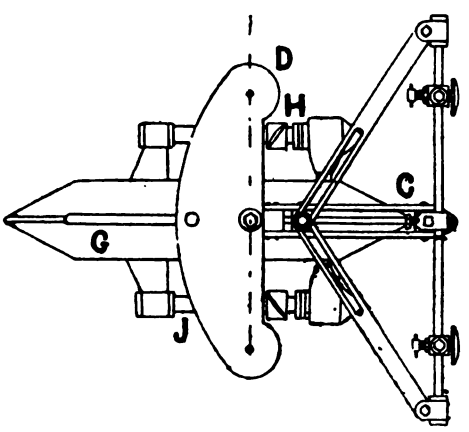

FIG. 2.

the stern of the boat; this spindle has at its lower end a second bevel wheel which gears with another upon a horizontal cross-shaft, and the latter drives by bevel gear the two propeller shafts. The boat is thus driven by twin screws. It will be seen that the whole of the case is free to swing about the top and bottom pivots so as to act as the rudder; an ingenious method has therefore been adopted to obtain stability when the boat is in motion. The propeller shafts are both hexagonal in cross-section, and the propellers are free to slide along them; it therefore follows that when the boat is travelling ahead the propellers are

Digitized by Google

working against one bracket, and when travelling astern are acting against the other.

The commutator is at the stern end of the case, and is provided with carbon brushes of square section, pressed against it by means of springs bent into a zigzag form. The armature itself is 3in. diameter, and the commutator 2¾in. diameter, in the size known as No. 1 type, and intended for a double sculler.

The field magnets consist of flat soft-iron plates bent into a suitable form so as to surround the armature, as shown in Fig. 3, and the winding is of the shunt type. The leads are carried up through the pipe which is connected to the rudder yoke, and they form the yoke lines used for steering, and pass to the secondary battery, which consists of 12 cells in two separate boxes. The cells are of the type made by the International Electric Storage Company, the plates being pasted on grids; they resemble the Theryc-Oblasser cells to some extent, and the plates are in celluloid envelopes. Each battery-box is of such a size as to go under the seat used for rowing, and the two boxes are connected

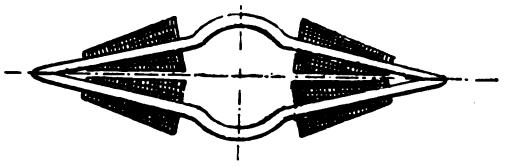

FIG. 3.

by concentric cable. Each cell has 11 plates, and the total weight of the battery is stated to be 112lb.; the motor at present weighs 60lb., but the makers are about to construct one which will weigh only 50lb. The external dimensions of each battery-box are 16in. long by 12in. wide by 6½in. high. When fully charged, sufficient energy is stored to run a boat containing four persons for eight hours. The speed of the armature when the machine is run in air is 2,000 revolutions per minute, giving a speed of 1,200 revolutions for the propellers, while in water the speed of the propellers is from 900 to 1,000 revolutions per minute. With four persons in a double sculler of ordinary type, the speed obtained in still water is said to be from four to five miles per hour.

One of these motors is at present on view at the yachting exhibition in the Aquarium. It is shown at work in a glass case filled with water. The adaptability of this motor to all ordinary rowing-boats, without necessitating structural alterations, appears to be a great point in its favour, as it can be hired out by boat proprietors.

THE DETERMINATION OF THE DRYNESS OF STEAM.

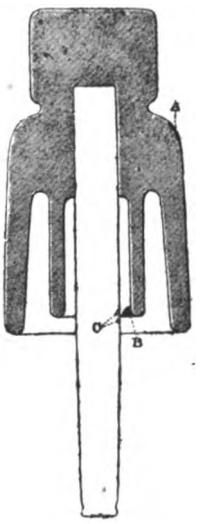
This subject was discussed before a meeting of the Institution of Mechanical Engineers last week in a paper presented by Prof. W. Cawthorne Unwin, F.R.S. Having described the various systems of ascertaining the dryness of steam, the author arrived at the following conclusion:

Generally, the author thinks, that the wire-drawing calorimeter without separator is the most convenient and accurate for steam with less than about 2 per cent. of moisture. For steam containing more moisture, the separating calorimeter without wire-drawing apparatus is accurate enough and convenient. The use of the separator and wire-drawing calorimeter combined is more troublesome, especially if, as is desirable, a condenser is also used to determine the amount of steam passing through the separator. In cases where there is much priming, it would seem best to take the whole of the steam through an ordinary steam separator, measuring the amount of water trapped, and then to test by a wire-drawing or separating calorimeter the dryness of the steam after passing the separator. In priming, much of the water probably flows along the bottom of the pipe, and it appears impossible that a sample can be obtained containing an average proportion of steam and water. It is recommended by Prof. Carpenter that the sample of steam to be tested should always be taken from a vertical, not from a horizontal steam-pipe. No doubt there is rather more tendency for water to flow along the bottom of a horizontal pipe than down the sides of a vertical pipe, but merely taking steam from a vertical pipe does not ensure freedom from error, especially if the amount of moisture in the steam is considerable. Variations in tests for wetness are doubtless often due to the difficulty of getting a true average sample of steam, and it would seem that errors are generally in the direction of underestimating the amount of moisture.

LIGHTNING AND TELEGRAPH INSULATORS.

The following case of lightning happened on the telegraph line between Bombay and Bhusaval in October last. Mr. P. V. Luke, director of the construction branch (Indian Government Telegraphs) has sent the appended note, which is given in the current issue of the *Journal*, on the subject to the secretary of the Institution of Electrical Engineers.

One of the iron wires was broken, and the cause put down to lightning. As no insulators were smashed, the local superintendent, Mr. Kenyon, called for the ends of the wire, and had two of the white porcelain insulators on each side of the break removed for examination. Of the four insulators, one was cracked and the stalk loose.



The other three appeared to be entirely undamaged, except that each had a little brown mark at the edge of the inner cup, in the position marked B in the accompanying sketch; and on each stalk, at C just opposite, was a small mark about the size of a pin's head, with a little conical point in the centre, where the flash had apparently sparked across. There was also a brown mark at A where the wire binder touched the insulator. At each brown mark the glaze of the porcelain was destroyed, being reduced to a powder which disappeared in water. The three apparently undamaged insulators were tested after being immersed in water for 24 hours, and each gave an insulation resistance of over 5,000 megohms. If the lightning went through the porcelain it would assuredly have destroyed the insulation; failing this, it must have passed over the whole surface of the porcelain to get from the line wire to the edge of the inner cup—which seems curious.

BRUSH CENTRAL STATIONS.

A handsome quarto-page pamphlet has been issued by the Brush Electrical Engineering Company, Limited, of 49, Queen Victoria-street, E.C., in illustration of the company's construction and installation of heavy electrical plant for central-station working. That the Brush Company occupy one of the leading positions in this branch of work goes without saying, and this fact is brought home

Digitized by Google

very forcibly to the mind by a perusal of the descriptions and by an inspection of the illustrations, contained in the pamphlet, of electricity works equipped by the company. The *brochure* details the central stations at Huddersfield, Hanley, Lancaster, Worcester, and Windermere. These do not, however, in any way imply the extent of the company's operations in this direction, but are only described by the aid of excellent photo-litho illustrations as typical examples showing the nature of the work. Thus, for instance, alternate-current steam-driven plant is installed at Huddersfield, where a Victoria motor operates an overhead travelling crane, and at Hanley the plant comprises alternate and direct current steam-driven machinery. The Lancaster station is equipped with direct-coupled dynamos. Coming to Worcester, one finds here the first example in this country of the utilisation of water power on a large scale in conjunction with turbines and steam-driven alternators; whilst at the same time alternating-current motors of 30 h.p. are used for driving a set of pumps at the waterworks. At Windermere the plant laid down also comprises alternators actuated by turbines, this being the first instance of the application of water power to the public supply of electricity. A glance at the map which follows shows that the Brush Company have established no less than 28 central stations in the United Kingdom—truly a remarkable record of progress. We must, however, not omit to mention that the company have also equipped the largest and most important central station in the country—namely, that on Bankside, from which the City of London Electric Lighting Company are supplying light to the greatest city in the world. The pamphlet, which also contains a list of numerous central stations carried out by the company in nearly all parts of the world, is exceedingly well illustrated, and it will be preserved by all who are fortunate enough to secure a copy.

AN ELECTRIC CARRIAGE IN PARIS.

A note concerning the use of his type of secondary battery for traction purposes has been kindly forwarded to us by M. D. Tommasi, of 44, Rue Jacob, Paris. He states that the trap equipped with this type of accumulator somewhat resembles a petroleum-cart, but that there is no mechanism visible. The battery is arranged behind the seat of the carriage, under the body of which a small motor is fixed. The carriage is provided with a powerful brake. It will be remembered that the Tommasi cell differs from other oxide of lead accumulators in the sense of being specially constructed. Each electrode is formed of a celluloid frame perforated by numerous holes, filled with active material, and in the centre is placed a lead core, which serves as the conductor for the current and not in any way as a support for the active material, as in other types of secondary batteries. This arrangement renders impossible, according to M. Tommasi, the disintegration of the electrodes and the falling of the active material. The electrodes of the same kind are soldered together to a connecting bar, and are separated from the adjoining electrodes by means of vertical rings made of celluloid. The case is of wood, lined internally with celluloid, and closed at the top by a tight transparent cover. The accumulator formed in this manner is compact and light, and its capacity is about 25 ampere-hours per kilogramme of electrode. The battery is claimed to be unaffected by shocks and vibration, and sustains, without inconvenience, extremely high rates of discharge. The trap already referred to is equipped with 21 cells, each weighing 13 kilogrammes 300 grammes, and contained in seven boxes. These cells are connected in series, and are capable of discharging on an average 100 amperes at 40 volts. On starting, and on steep gradients, the discharge rises to 200 amperes. Under these circumstances, the battery works for an hour and a half, which corresponds to a capacity of

7·5 ampere-hours per kilogramme at low discharge
11 „ „ „ „ „ average „
15 „ „ „ „ „ maximum „

Under more reasonable working conditions the capacity would be much higher—that is to say

22 ampere-hours at the rate of 1 ampere per kilogramme
18 „ „ „ „ „ 3 „ „ „
15 „ „ „ „ „ 6 „ „ „

The total weight of the trap, including passengers, is about 1,200 kilogrammes, or, say, 24cwt., and the speed attainable is 20 kilometres (12·4 miles) an hour. Both stopping and starting of the carriage are easily accomplished. M. Tommasi states that the elasticity of his accumulators combined with their great capacity forebodes well for the future success of electric traction on roads.

ARC LIGHT CARBONS.*

BY B. F. MILES.

(Concluded from page 108.)

We have now reached what is called the "green carbon" stage of the process. The carbons appear a shiny black in colour, are quite heavy, break easily, and when held by the fingers and tapped together, give forth only a dull sound.

Both moulded and forced carbons are next taken to the furnace-room, where the volatile matter contained in them is driven off. This is a process requiring great delicacy in handling combined with absolute thoroughness. If they are baked too rapidly, they warp and so are unfit for trimming. If they are not baked sufficiently, they are too low in conductivity and give a very poor light.

In the early days of the art baking was accomplished by placing each carbon in a mould or crucible, and heating many crucibles in a large retort. This very expensive process was soon superseded by baking in fireclay pots or seggars, many of which can be baked together in a furnace resembling a pottery kiln. This is the process followed by many foreign manufacturers. In this country the almost universal practice is laying the carbons in a large rectangular furnace, layer upon layer, each separated, in a bed of sand, the entire mass protected by a covering several inches in thickness, over which the heat plays until every carbon has reached a high temperature. Just what temperature this is, measured in degrees, has never been accurately ascertained. It is supposed to be between 2,000deg. F. and 3,000deg. F. Few realise the time required in baking alone. It seldom happens that large furnaces are "turned" within two weeks.

There are several methods of applying heat, both to calcining retorts and baking furnaces. The simplest construction consists of a fire-box in which coal or natural gas is burned and the heat carried over the mass of carbons in a single direction.

Mr. Lawrence has invented a modification of the Siemens-Martin reverberatory process for steelmaking which gives the highest results. Bituminous coal, rich in gaseous products, is converted into fuel gas. This is conveyed hot into the furnace itself through firebrick flues, first by one end, next by the other, where, mixed with air, it burns with an intense flame. During the two or three days of highest combustion, the interior of the furnace glows like the face of the sun at noon, but at the same time the heat is under most perfect control.

From the furnace the carbons are carried to the sorting tables, where, rolled on steel plates of true face, the straight are separated from the crooked. The former are taken into the plating-room, where they are given a thin coating (usually) of copper, which increases their conductivity and prolongs their life. The latter are sorted into various grades: some are sold as seconds, others are cut into short lengths, others are rejected. It is a very interesting sight to see the packing boys wrapping the carbons in paper for shipment. Few machines surpass their agile fingers in rapidity of movement as they roll single carbons into blocks of five, and blocks of five into packages of 25. The latter they place closely together in wooden boxes of a thousand capacity, and when the nails of the lid are driven down the carbons are ready to be carried by rail or water to any part of the civilised world.

* *The Electrical World.*

Digitized by Google

There remain two or three points of interest to students of social science and statisticians.

At the beginning of the modern carbon industry in 1878 nearly every one of its 30 to 40 processes was accomplished by unaided hand labour. In 16 years this condition has been completely reversed. Hand labour now exists only in four processes, and in the coming year these will be greatly assisted or accomplished wholly by labour-saving devices.

Such economies are only possible where the business is carried along on the largest scale. In such a concern the responsibilities thrown upon its management are great. The workman whose employment fails should be provided for. This can seldom be done in these days of fierce competition save by increase in quantity, consequent upon the highest quality. It is greatly to the credit of Mr. Lawrence that this is his invariable aim, and that, with his many improvements in processes and machinery, he has been able so to extend the operations of the company of which he is head that it has retained in its service all its worthy employés.

Few industries exemplify better the tendency of our age to concentration. During the past 15 years nearly 75 factories have started in this country and Europe to compete for the production of the 200,000,000 carbons annually consumed. Their combined capacity has probably reached five to six hundred millions per year. At no time has available active factory capacity decreased below 300,000,000 annually. Over half of these factories have died natural deaths. Of the remaining, many have amalgamated with competitors to reduce costs. At present about 25 factories are in operation, with a capacity of 350,000,000 to 400,000,000. Of these, over one-half are unable to find sufficient trade to justify an output of 1 per cent. of the world's consumption. Of the remaining dozen, less than one-half produce nearly 90 per cent. of the grand total.

EARTHENWARE CONDUITS FOR ELECTRIC LIGHT MAINS.

London is not—as may, of course, be readily supposed—by any means the only place where trouble has arisen in electric light supply operations from the ingress of moisture, coal gas, foul air from the sewers, etc., into the conduits for street mains where such are employed: conduits, that is, of the open type in which bare copper mains are stretched upon insulators.

It will be remembered that in the French metropolis one of the principal types of conduits employed—especially for the bare copper mains—is of rectangular section in concrete: and, of course, where this has been properly carried out, there is not much trouble to be feared, the chief danger being from imperfect top coverings, which allow moisture to creep in. In many cases, however, it is impossible to use this form of conduit, owing to the small width of the pathway, already encumbered by the numerous pipes, etc., of other distribution systems. Recourse has been had under these conditions to rectangular conduits in earthenware of considerably smaller sectional area, but practical results show that the pottery conduits thus installed involve serious losses by leakage, with other disadvantages—so pronounced, indeed, that they have now been taken out entirely and replaced by concrete conduits of a size as large as may be permissible in the narrow space under the footpaths. The entire system of one company is thus formed of cement concrete trenches, and satisfactory working at last obtained.

According to M. Monmerque, who discusses the matter in *L'Eclairage Electrique*, the earthenware conduits, however carefully put down and maintained, were positively filled up after a time with white deposits of an alkaline nature, containing, as was proved by chemical analysis, a large quantity of pure sodium—in sufficient quantity, indeed, to burn violently on coming into contact with water.

The causes of such a phenomenon are not clear, though a number of possible reasons have been offered in explanation. One suggestion is that the salt, used very largely in Paris in winter time to melt the snow in order that the streets may be swept clean, is responsible for the damage; but it is objected against this hypothesis that the salt solution is used on the roadway and not on the footpaths, whilst the melted snow and slush is at once swept into the gutters and thence into the sewers, giving no time for soaking through the subsoil. Moreover, fresh water only is used to flush the streets, and the salt would therefore be so diluted that the small quantity which might conceivably reach the interior of the conduits would hardly account for the large deposits therein found. The footpaths themselves are washed down with fresh water only, and this cannot offer an adequate reason.

A suggestion which has undoubtedly some degree of ingeniousness has been made with regard to the conduits themselves. It is thought that the glazing of the interior—obtained, as is well known, by the agency of common salt—may have played a by no means unimportant part in the curious results chronicled. It is, of course, impossible altogether to avoid the entrance of moisture into the conduit, and if electrolysis be set up through slight leakage of current, there might easily result an increasing amount of disintegration in the glaze. A somewhat similar result has been noticed in one of the London distribution systems employing a cement conduit or concrete trench: in this case the negative wires of feeders or potential equalisers were found to be so thickly coated with a whitish mineral deposit as to practically destroy all its insulation. Possibly some of our English earthenware-makers, especially those who have adopted the manufacture of pottery conduits for electric light mains, will be able to criticise the above hypotheses, or suggest others of a more tenable nature.

COMPRESSED AIR VERSUS ELECTRICITY.

A note dealing with the comparative efficiencies of electric power and compressed air was presented by M. Badois to a meeting of the Société des Ingenieurs Civils de France on the 18th ult. The author, in criticising a paper read recently before the same institution by M. de Marchena, said that in order to logically compare electricity with compressed air each system must be considered according to the same transport unit. M. Badois took as his unit a self-contained car having accommodation for 50 passengers. In this respect he showed in the case of electricity that there was not the exact correlation between the elements of information collected by M. de Marchena and the estimates of cost of motive power formulated by him. M. Badois contended that the ratio between the power utilised on the car axle and the motive power indicated in the steam-cylinders at the central station, or, in other words, when the final efficiency in ordinary working was only 25 to 30 per cent. (instead of 30 to 40), the consumption of coal per car kilometre in the case of the self-contained car carrying 50 passengers could not be reckoned at less than 3 kilogrammes to 3·30 kilogrammes (not 2 to 2¼ kilogrammes). The power absorbed on an average per kilometre would be equivalent to about three horse-power hours. These figures, M. Badois stated, are confirmed in the case either of the trolley, accumulator, or the third-rail system, by a careful examination of the practical results cited by M. de Marchena, provided, of course, the results are brought to the unity of transport already referred to. With regard to the use of compressed air for traction purposes, he stated that the theory set forth by M. de Marchena would lead to a final efficiency at the axles of 18 to 20 per cent. only of the power indicated by the steam-engine at the station. But this theory must be transgressed, since the results frequently repeated at Nantes and at Nogent showed efficiencies of between 35 and 40 per cent. M. Badois believed that, instead of considering compressed air as an agency of transforming heat into work, it should be regarded more simply and more exactly as a mechanical spring. The conclusion, M. Badois said, is that one may expect to obtain a final efficiency of 57 per cent. from compressed air, and not 18 to 20 per cent., as limited by the theory advanced by M. de Marchena.

THE MECHANICAL AND ELECTRICAL REGULATION OF STEAM-ENGINES.

Before the Institution of Civil Engineers on Tuesday, Sir Douglas Fox, vice-president, in the chair, a paper was read on "The Mechanical and Electrical Regulation of Steam-engines," by Mr. John Richardson, M.I.C.E., of Lincoln.

The author dealt with the regulation of steam-engines from the steam users' point of view, and showed how, although many excellent means existed of automatically governing steam-engines to secure regularity and economy, yet in many cases these means were ignored. After laying down the conditions essential for first-class governing, the author reviewed the construction of engine governors, from that invented by Watt to the latest examples, the principal types being illustrated. The advantages and disadvantages connected with each were pointed out, and the unsuitableness of the ordinary pendulum governor for the modern engine, which required controlling with much more certainty and delicacy than was formerly necessary. Moreover, the high speed of textile machinery made regularity an absolute necessity, and the requirements of engines for producing electric light were especially exacting. The type of governor selected as being most suitable was that which combined revolving weights with a spring, and a governor was described which, while of moderate dimensions and weight, had still great lifting and thrusting power, combined with such a balance of its parts that the working sleeve was raised from the lowest to the highest position with but slight variation in speed.

The author next referred to the various kinds of valves for controlling the admission of steam, and their action with the governors. First, the various type of throttle-valves, and the results of experiments in connection with them, and the engines for which they might be properly used. The methods of regulating steam-engines by altering the travel and angle of the main slide-valve, or by limiting the admission of steam by controlling the angular advance and travel of a cut-off slide working upon the back of the main valve, were dealt with. The types of governors suitable for controlling such valve action were described: for instance, those fixed on the crankshaft and revolving with it, and others driven by a belt and gearing at a distinct speed from the crank. Illustrations of this class of valve gear were given, together with copies of diagrams taken from engines so fitted, and the results of experiments as to variation in speed. This gear was stated to be suitable for engines of moderate size, where the working pressure was under 100lb. Tables giving comparative tests taken under equal conditions between engines fitted with shaft governors controlling the slide-valve, and speed governors controlling a throttle-valve were exhibited, showing the advantage of the automatic governor both as regarded regularity and power.

Link expansion gears were next described, in which the main valve had a constant lead, compression and exhaust, and it was the cut-off valve working on the back of the same only which was varied. It was shown that the success of this kind of valve gear depended very much upon the type of governor used in connection with it, which, besides delicacy, must have a wide margin of stability and strength, as considerable power was required to operate the working parts when the engines were of moderate size. The necessity for dispensing with dashpots to prevent oscillation of the governor by the link was insisted upon, and the type of governor which could control such valve gear and maintain perfect stability at all points was exhibited.

The much higher pressures necessary for the most economical use of steam, compelled the employment of valves which would work in equilibrium, or nearly so. These were mainly of three kinds: piston-valves, rotating or circular, like the Corliss, or double-beat valves, slide-valves requiring too great a part of the power of an engine working with high-pressure steam. After alluding to other classes of valve gear, the author described a cylinder fitted with two double-beat admission valves and two gridiron exhaust-valves. It was shown how each of these valves was susceptible of independent adjustment, even while the engine was running, and a simple method of varying the cut-off of the admission valves by the governor was explained and illustrated by a working model. With a valve gear of this kind there was absolutely no strain upon the governor, and not the slightest tendency for it to work or jump due to the working of the valve gear. Diagrams taken from engines fitted with this gear were exhibited, in which the range of cut-off extended from zero to seven-eighths of the stroke, the peculiar advantage of this gear being that it allowed of the engine being instantly stopped from any part of the mill or factory in which it worked.

The electric regulation of engines was next dealt with. The conditions which obtained for an engine driving a dynamo were not quite the same as those for maintaining a constant speed of other machinery; as, if the electric current produced by the engine were used to control its speed, it became possible either to run the engine at a practically uniform speed in connection with a perfectly compounded dynamo or to run it at a varying speed, maintaining either a constant difference of potential with a varying current or a constant current. Further, it was shown that by utilising the changes in the current to control the engine, it was possible when the load was suddenly decreased to effect what was impossible with a speed governor—namely, to shut off for a time the whole of the steam supply before the engine had had an opportunity of increasing its speed. A number of appliances which had been devised during the last 15 years and tested for electrical regulation were described, some as examples of what should be avoided, and others as successful. In most of these latter a solenoid, the core of which was held in a varying position within it by the current, was connected in different ways to the valves. Two forms of electric motors for altering the position of valves were also shown, and other forms of relays. The advantage of the direct connection of the solenoid was very great over any other form of relay.

The paper concluded with a description of a method of electric control of a valve gear which was suitable for engines of large size, the power required to govern the lever being practically nil, a small solenoid and a slight current being found sufficient to effect the entire control of engines up to 1,000 h.p. An automatic method of stopping or slowing the engine, should there be an accidental breaking of the governor circuit, was also illustrated by drawings and working models.

THE GENEVA ELECTRIC TRAMWAY.

During the past five months an electric tramway service has been provided at Geneva by the Compagnie Générale des Tramways Suisses, who entrusted the work of equipping the lines to the Compagnie de l'Industrie Electrique, of Geneva. The tramway, which has been laid in the most frequented part of the town, puts into direct communication the aristocratic quarter of the Bastions and the Place Neuve with the Cornavin railway station; and in the suburbs it extends as far the Champel Plateau on the one hand and to the village of Petit-Saconnex on the other. The total length of the route is about 3½ miles. Besides this, a double line, one mile long, connects the Place du Theâtre with the depôt, situated at Cluse, near Carouge. The former is a single line with turn-outs at suitable intervals. The generating plant has been erected in the municipal central station of the Forces Motrices du Rhône. There are two self-exciting Thury dynamos coupled direct by means of Raffard flexible couplings to two turbines of the Piccard horizontal type. One set of machines is sufficient for dealing with the present service, the other set being kept as reserve. Each generator is a compound dynamo, capable of giving 150 kilowatts at a speed of 365 revolutions per minute. Leaving the distributing and regulating boards, the current is conveyed by means of an underground cable to the central part of the tramway system. From here the current is divided, one part going in one direction and the other in the opposite direction. Connections are made at intervals with the overhead trolley wire, lightning arresters being provided at each junction.

Digitized by Google

In the town the trolley conductor is formed by a galvanised steel wire, 7mm. in diameter, so as to render it capable of withstanding any test it may have to contend with, and in the open it is of copper. The trolley wire is arranged in the middle of the thoroughfares, either on standards at a height of 20ft., or is supported by means of transverse span wires fixed to posts on the pavement or to brackets attached to the walls. The return is formed by the rails assisted by a supplementary copper wire connected to them at intervals. The track in the town is formed of Marsillon rails laid on wooden sleepers; elsewhere, Phœnix rails are used. The gauge is 4ft. 10in., the maximum gradient is 55mm. per metre, and the minimum radius of the curves is 25 metres. There are eight cars in service, each capable of accommodating 32 passengers, and each being equipped with a motor of either 15 h.p. or 20 h.p. The speed is 7½ miles in the town and 12 miles in the suburbs. The tramway has met all the requirements of the locality.

THE INCANDESCENT LAMP.*

BY MANNING K. EYRE.

(Continned from page 138.)

It is evident that there is a limit to the amount of treatment to which a fibre can be subjected, since the filament of the lamp must be a given resistance for a certain candle-power, voltage, and efficiency. In practice the amount of treatment reduces the resistance considerably. Knowing the resistance required in the finished filament, it is only necessary to treat until this resistance has been attained. By the side of the ammeter in Fig. 2 are shown the mercury gauges for indicating the pressure in the treating jar. It was long ago found that to treat under atmospheric pressure did not give satisfactory results, the operation being performed too quickly, and the deposit consequently rough and soft; a pump is therefore connected with the jar to exhaust it. When the gauges show sufficient vacuum the carbon vapour is admitted. The deposit under these circumstances is much more uniform and hard. The time required to treat each set of filaments is for heavy carbons as much as 50 to 60 seconds, and less for the lower candle-powers. In this, as in all the other processes of manufacture, there are numerous uninteresting details requiring the greatest possible care and attention. Were the resistance of carbon constant at all temperatures, the process would be greatly simplified. As the temperature rises, however, the resistance diminishes, which is contrary to the law followed by metals, whose resistance increases with an increased temperature. Therefore, if we are treating two filaments to a given resistance, and treat one at a different temperature from the other, the results will not be the same, though the final resistances are. If the two filaments are now tested at the same voltage, it will be found that they differ in candle-power. This and other difficulties that might be cited can only be overcome by years of experience, skilled labour, and the best quality of apparatus.

The user of lamps can perhaps now understand why, if a number of lamps are run through the factory, say, for 16 c.p. 106 volts, only a portion of these lamps can be furnished of that particular voltage, the balance varying in voltage from about 100 to 102. I have been occasionally asked by central-station people why lamp manufacturers did not endeavour to have all plants installed at three or four voltages. It is evident that if this plan were adopted a large part of the product of the lamp factory would be unsaleable, there being no market for lamps unavoidably manufactured of other than the three or four voltages installed. Of course the immediate effect would be increased cost, and the user would have to pay for the unsaleable product.

The filament being now completed and ready for assembling, we can turn our attention to the glasswork. In Fig. 1, the "inside part" and bulb are shown in various stages of manufacture. The inside part, *b* (Fig. 1), is first a small cylindrical glass tube. Sketch 1, Fig. 3, shows the process known as "flaring," which consists of widening out one end. In the meantime other labour is busy getting the wires ready. Each leading-in wire is composed of two metals, copper and platinum, the former metal being satisfactory for that part of the wire which does not enter the vacuum of the lamp, platinum being necessary for this purpose. Were the wire made entirely of copper, on heating the junction of the copper and glass the difference of expansion of the two substances would cause the glass to crack, resulting in a leaky lamp. Platinum, having very nearly the same coefficient of expansion as glass, obviates this trouble, and, in addition, possesses the advantage of being able to stand the high temperature of the blow-pipe. The copper and platinum are joined by fusion. Only a short length of the latter is necessary.

Sketch 2, Fig. 3, shows the next step in the process of assembling the parts. The two wires are inserted in the "inside part," the blow-pipe flame heating the inner end of the tube, and when the glass is sufficiently soft the operator, with a pair of flat pincers, seals the glass tightly together over the junction of the copper and platinum. This completes the "inside part" (see *b*, Fig. 1). Care must be taken in this operation to prevent cracking the

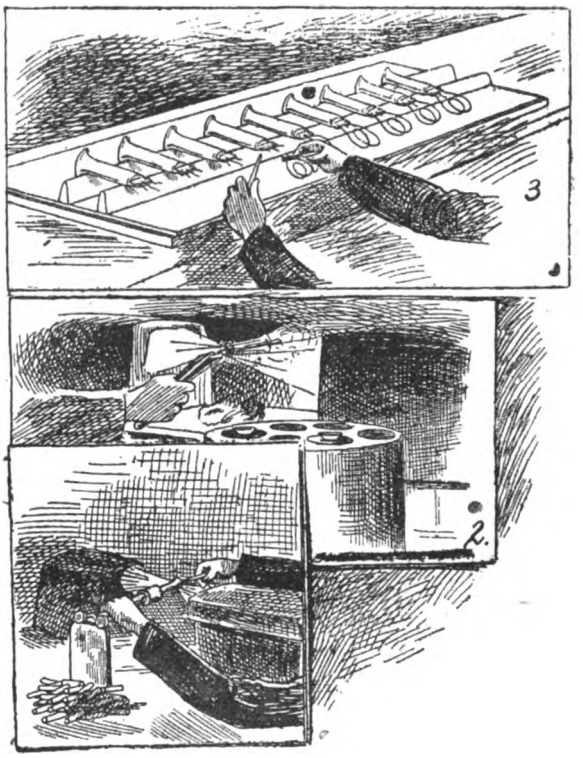

FIG. 3.—Manufacture of Inside Part.—1. Flaring. 2. Sealing in Wires. 3. Clamping.

seal, carelessness in this respect being a prolific source of leaky lamps, which are readily detected in the pump-room, where lamps are exhausted. To prevent this as far as possible, the glass is gradually cooled in an annealer, shown in 2, Fig. 3, after being subjected to the high heat of the blow-pipe. The inside part is now ready to receive the treated filament, the joining of the two together being a comparatively simple operation, commonly called "clamping," shown in 3, Fig. 3. The junction of the filament and the platinum wires may be made by means of a carbon paste, only the two legs of the filament being held in position until they adhere, or a more difficult operation may be employed, using a deposited clamp. The latter is made by heating the junction of the filament and leading-in wires in hydrocarbon gas, being much the same in principle as the treating process. Other methods have been and still are used, as, for instance, the socket joint, where the filament fits into a sleeve of carbon, carbon paste being used to make the junction firm. In another department the bulbs are being prepared for the reception of the inside part and filaments. As bulbs are now very generally moulded, it will not be necessary to describe the operation of blowing the bulbs. These arrive at the factory from the glassworks, as shown in the first sketch, *d* (Fig. 1).

The first step in handling the bulb is known as "tubu-

* The *Electrical World* (New York).

Digitized by Google

lating," which consists in attaching to the large end of the bulb a small tube, through which the lamp is later exhausted. This may be accomplished either by heating the rounded end of the bulb in the blow-pipe and at once working the small tube on the softened glass, or by first perforating the grounded end. In the latter operation the worker holds the bulb in one hand and the small exhaust tube in the other, and after heating with the blow-pipe, works them together, the tube fitting over the orifice previously made. The second operation is blowing off a part of the long neck to make the bulb of proper length. This process can be seen in Fig. 4, Sketch 1. The bulb is laid on revolving rollers, *c*, causing the bulb to revolve, while the flame from the pipe heats the neck at the point where it is to be blown off. When sufficiently hot, the bulb is lifted off the rollers, and the neck pulled off by hand, leaving a ragged edge. The operator then blows into the exhaust tube, and the ragged edge is blown out (presenting the same appearance as a soap bubble) until so thin that it can be rubbed off with the finger, leaving a clean, well-defined end (see Fig. 1).

The bulb is now ready for the inside part and filament, which are sent over from the clamp-room, after being carefully inspected. The process of assembling the bulb and inside part is called sealing-in, and can be seen rather crudely indicated in 3, Fig. 4. The blow-pipe flame is,

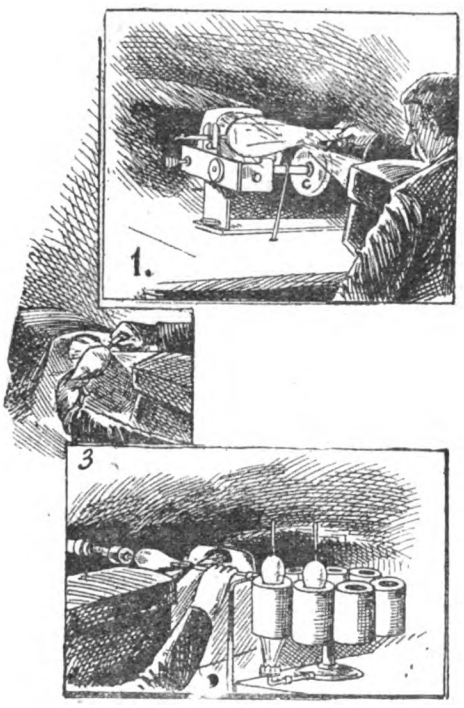

FIG. 4.—Manufacture of Bulb.—Blowing off Bulb.—2. Tabulating.—3. Sealing in

as usual, the means employed. The inside part, with carbon clamped to it, is taken in a holder and inserted in the bulb. The two are then placed in a frame which is slung into the flame. When the glass is softened the frame is swung clear of the flame and the holder inserted in the lower end of the inside part, the operator straightening the inside part and filament until they are in their proper position, as seen in the finished lamp. The bulb is then again lowered into the flame and kept rotating. The glass around the neck of the bulb gradually softens until by its own weight it falls around the flare of the inside part, forming an airtight seal. To prevent sudden cooling, the bulb is then placed in an annealer.

The sealing-in having been completed, the next step is the exhaustion. This is perhaps the most interesting and important process in the manufacture. Too much care cannot be devoted to it, for the quality of the lamps depends on the issue of this operation. It is, of course, understood that a vacuum is necessary to preserve the life of the filament, but perhaps everyone does not know how perfect the vacuum must be, the presence of only a little air oxidising the carbon, burning the filament, and shortening the life of the lamp. It was here that the early lamps failed almost entirely, the vacuum obtained by means of a mechanical air-pump being utterly insufficient. All the pumps now in use are mercury-pumps, generally Geissler or Sprengel pumps. The process of thorough exhaustion is so expensive that many means have been tried to make only a partial exhaustion answer the purpose. Mr. Gilbert S. Ram, A.I E.E., has expressed the whole matter so clearly in his work on the manufacture of the incandescent lamp that I think it would be interesting to the reader to quote him: "It has, at various times, been proposed to fill the bulb with nitrogen gas, and then to only partially exhaust. In this way a residual atmosphere of nitrogen could be left behind, which would be incapable of burning the filament. Another advantage of this method would be that the exhaustion, not requiring to be carried to a very high state, could be done very quickly with a mechanical air-pump. There are, however, several reasons why this method cannot be successfully used. The combustion of the filament with the oxygen in the case of a residual atmosphere of air is not the only action to be considered. In a lamp containing a residual atmosphere of air, nitrogen, or any gas, there are convection currents set up in the gas within the bulb, which consequently becomes very hot. The gas is heated by contact with the white-hot filament, and a continual circulation is kept up from the filament to the bulb, and back again. . . . . One of the most cherished attributes of the incandescent lamp is that it gives off very little heat, and is perfectly safe, and can be handled with impunity when lighted, and may be placed with safety anywhere, even with very inflammable material in close proximity. All these advantages are lost when the vacuum is not perfect. No residual gas can be allowed in the bulb."

(To be continued.)

GOVERNING OF STEAM-ENGINES BY THROTTLING AND BY VARIABLE EXPANSION IN CENTRAL ELECTRIC LIGHT STATIONS.

BY CAPTAIN H. RIALL SANKEY.

Before the Institution of Mechanical Engineers last week a paper by Captain H. Riall Sankey, of Thames Ditton, dealing with the governing of steam-engines by throttling and by variable expansion, was read. Discussing the question from the point of view of engines for electric lighting purposes, the author said:

Electric Light Engines.

In a well-designed central station there will be a number of engines principally of one size and a few smaller engines. The fluctuations of load, although rapid at times, are approximately known beforehand, because they follow with more or less accuracy a previously ascertained load curve. It is therefore possible at all times so to work the engines that the load on those running is approximately their economical load. Under these conditions, expansion governing has no advantages if the engines are working non-condensing; because in this case the economical load is obtained with so high a mean pressure that, except with unusually high boiler pressures, the highest mean pressure that can be obtained gives the best economy. If, however, the engines are condensing, the conditions are considerably changed; because, as already seen, although the economical load is now obtained with a much lower mean pressure—namely, from 28lb. to 32lb. mean pressure according to the boiler pressure—a much greater mean pressure is possible, and it may be expedient to provide for using it. Supposing that the engines are mechanically designed to be able to run continuously with 40lb. mean pressure, and for short periods with 50lb. mean pressure, it is then possible to run them at powers materially greater than their economical load, and this tends to economy, because on a rising load fresh engines can be started later and with more deliberation, and on a falling load superfluous engines can be stopped sooner. In order to work the engines in this manner—that is, with best economy at 28lb. to 32lb. mean pressure and with power to overload—it is obviously necessary to be able to alter the cut-off. Hand gear would in this instance answer the purpose, but automatic expansion gear is undoubtedly preferable.

In order to obtain some idea of the economical gain of expansion governing under such circumstances, the following example has been worked out. The load curve chosen is that for 24 hours at the Kensington electric light station on December 2, 1890, which was first published by Mr. Crompton in his paper read before the Institution of Civil Engineers on April 7, 1891

Digitized by Google

(*Proceedings*, vol. cvi., page 7), and which has done duty many times since. It is assumed that each of the principal engines in the station is capable of developing 140 e.h.p. with 40lb. mean pressure in the cylinders, and that there are two smaller engines, each capable of developing 70 e.h.p. with the same mean pressure: these are somewhat larger units than those actually in the station. It is also supposed that the pressure available at the engines is 150lb. absolute per square inch.

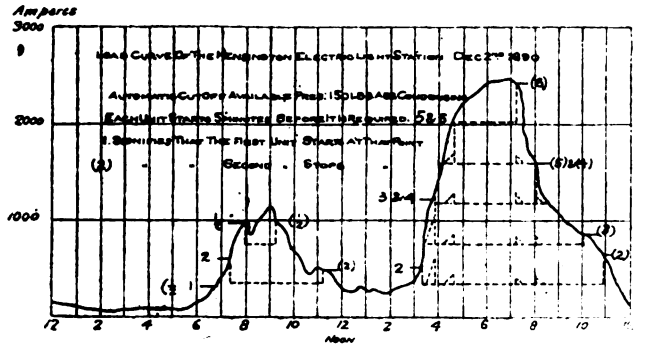

FIG. 1.

Fig. 1 shows the times at which the different engines would be started and stopped when the governing is done by the throttle, the cut-off being arranged for a mean pressure of 34lb. per square inch; and from this, with the help of a constant-expansion steam-consumption straight line, the water required to be evaporated for the engines only can be calculated, and is found to be 110,330lb. for the 24 hours.

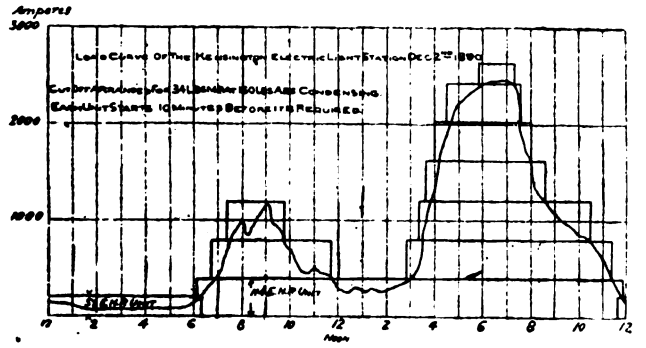

FIG. 2.

Fig. 2 shows the effect on the times of starting and stopping when the engines are governed by the cut-off, and are allowed to be overloaded up to 50lb. mean pressure for half-an-hour, assuming that the dynamos are designed to stand this overload. As before, the total water required in 24 hours can be calculated with the help of the constant-pressure consumption curve, and it works out to 87,240lb.

In the particular instance here chosen it will be seen that at the time of maximum load six units are running with expansion governing as against 6½ with throttling. This points to the fact that expansion governing tends to reduce the number of engines required in an electric light central station; in other words, it can better be afforded to overload engines with expansion governing than engines with throttle governing, for in the former event the economical ill effects of the overload are temporary, while in the latter they are permanent. On the whole, therefore, it can be stated that for large central electric light stations, when working non-condensing, throttling is as good as expansion governing; but when condensing, governing by the cut-off has a superiority.

An electric light station containing only one engine will evidently be worked most economically by altering the cut-off, if the engine is condensing. If the engine is non-condensing, the case is not so clear. A great deal depends on the boiler pressure that can be obtained, and it will be observed that the power of overloading the engine is not of much advantage, because in all probability the time of overload would last too long to be permissible, unless there were a peak in the load curve, in which case, of course, expansion gear would be of use. Thus one of the factors determining the relative merits of the two methods of governing, as applied to this particular kind of work, is the shape of the load curve; but as it is impossible to know beforehand what the shape will be, it is best in practice to arrange the engine with expansion gear, because this will meet all cases, whereas throttle gear will not. In electric light stations of medium magnitude, containing, say, three or four engines, throttle governing will give as good results as expansion governing if working non-condensing; if condensing, expansion governing will be best.

Dynamo Engines for Transmission of Power.

Many different cases occur, depending on the number of motors and on the kind of work to be done; and the difference will be expressed by the shape of the load curve. When there are many small motors which are not frequently started and stopped, changes in load will take place gradually; the load curve will be fairly regular, and in shape not unlike that for electric light stations: evidently, then, the same remarks apply.

A somewhat unusual case and difficult to deal with is that of a single motor driven by a single dynamo, the latter in its turn driven by a single engine. The first difficulty is met with on starting the motor, especially if it has to start with even a small load on it. The torque, or turning moment, required for starting is great, and if the engine is governed by the throttle, the maximum torque which the engine can give out is reached sooner than if the engine is governed by the cut-off, because the latter allows of momentary excessive overload. The second difficulty occurs whilst the machinery is running, should the load fluctuate considerably in the neighbourhood of the full load. If the engine is governed by the throttle, directly the full load is overstepped the speed of the engine must drop. The available horse-power will thus be diminished, and if the load remains only for a short time above the full load, it must inevitably pull up the engine, or, rather, it would do so were it not that the fuses in the circuit would blow, owing to the abnormal increase in the current due to the reduction of counter E.M.F. in the motor. If, on the other hand, the engine is governed by the cut-off, the overload on the motor will be met by an overload on the engine, and the difficulty will disappear. This is evidently a case where expansion governing is far preferable to throttling, and, in fact, may be said to be necessary: although throttle governing could be made to answer, by fixing the cut-off late enough, but then the economy of working would be greatly reduced.

Electric Tramways and Railways.

The most important case, however, is that of electric tramways and railways. A glance at the typical load curves illustrated in Figs. 3, 4, and 5 will show that the machinery cannot be worked like that of an electric light station; that, in fact, all the engines, except the spare ones standing in reserve, must be kept running, and that they are alternately fully loaded and lightly loaded at short intervals of time. The power of being able to overload the engines for a short time, as can be done with expansion governing, is here of the utmost importance, especially from the economical point of view; and there is the incidental advantage, as previously explained, that expansion gear responds more readily to sudden changes of load. This being so important a case, it may be well to illustrate it by a numerical example. Figs. 3, 4, and 5 are typical load curves for 10 minutes on an electric railway; and it will be noticed that in each of the three figures a peak of the same height is shown at A, so that the same number of engines have to be worked in each instance. It is proposed to calculate the water required to be evaporated for the engines during each 10 minutes under the following five different conditions: (1) the engines are governed by the throttle-valve with the cut-off arranged for 35lb. mean pressure, when the full available pressure is used; (2) the engines are governed by the throttle-valve with the cut-off arranged for 45lb. mean pressure, when the full available pressure is used; (3) the engines are governed by the throttle-valve with the cut-off arranged for 50lb. mean pressure, when the full available pressure is used; (4) the engines are governed by the cut-off; (5) the engines are governed by the cut-off from 20lb. mean pressure upwards, and by the throttle-valve from the same mean pressure downwards.

In Fig. 3 there are three peaks of nearly the same height as A, and the engines are comparatively well loaded during the whole 10 minutes. In Fig. 4 the other peaks are of medium height, and this figure represents a medium load on the engines. Lastly, Fig. 5 denotes only a light load on the engines. It will be supposed that each engine is capable of developing 980 i.h.p. at 35lb. mean pressure, 1,260 i.h.p. at 45lb., and 1,400 i.h.p. at 50lb. mean pressure; further, that the engines are condensing, and that the full available pressure is 150lb. absolute. It will then be possible to use the consumption curve given in Fig. 6.

In the first case, throttle governing with the cut-off arranged for a maximum of 35lb. mean pressure, it is necessary, as shown in Fig. 3, to keep six engines running; and since they are working with constant cut-off, the consumption at all loads will be represented by a straight line, and therefore the total actual consumption will be the same as if the engines were working under a constant load equal to the average load.* For the 10 minutes under consideration the average load is found to be 3,116 i.h.p.; hence the average mean pressure is 35 × 3,116

* This result follows at once from the Willans straight-line law; and, moreover, the author obtained an experimental proof, as mentioned in his remarks upon Dr. Edward Hopkinson's paper on the City and South London Electric Railway (*Proceedings* Inst. C.E., 1893, vol. cxii., p. 263).

* The figures in these columns are the percentage increase in water consumption compared with the fifth arrangement.

$\div(6\times980)=18{\cdot}55$lb. per square inch. Referring to Fig. 6, it will be seen that the water consumption of the standard-consumption engine at this mean pressure is 312lb. per hour; hence the total consumption for the 10 minutes is $(311\div6)\times6\times980\div35=8{,}740$lb. The water consumption for Figs. 4 and 5 can be found in exactly the same way, and the result is given in Table I.

In the fourth case—expansion governing—the consumption for the short-period heavy load will evidently be the same as in the third case, but owing to the cut-off being altered, considerable economy is obtained at the lighter loads at which the engines do most of their work. The total water cannot in this case be obtained from the average mean pressure, because the consumption line is no longer a straight line, but has to be

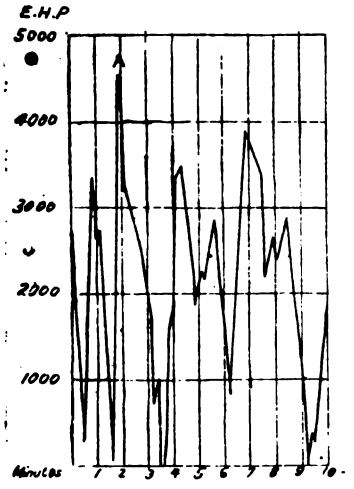

Fig. 3.

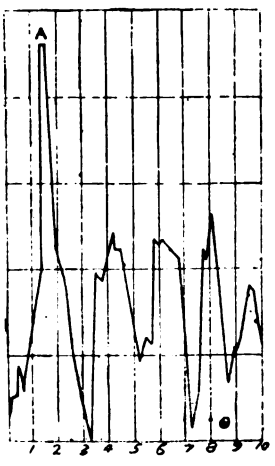

Fig. 4.

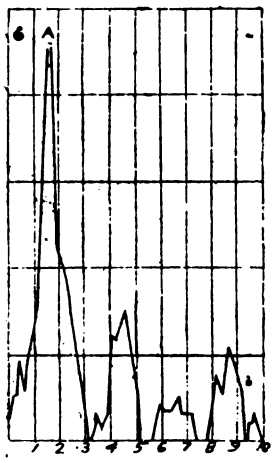

Fig. 5.

In the second case—throttle governing with the cut-off arranged for 45lb. mean pressure—it is found that this increase in the available power of each engine allows of stopping one engine, keeping only five running. The consumption of each engine is now represented by the Willans line W_2, and is greater than in the first case; nevertheless, the total consumption is less than in the first case, as shown in Table I.

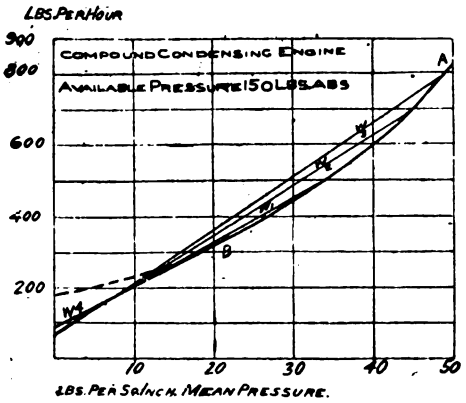

Fig. 6.

In the third case—throttle governing with the cut-off arranged for a maximum of 50lb. mean pressure—only four engines are required, because they can now develop for short periods a sufficient power; but as the cut-off must be later the consumption at all loads will be greater, as shown by the Willans line marked W_3, in Fig. 6. The average indicated horse-power, however, is smaller, because the losses in the dynamo and engine of the fifth and six set are saved. The average thus becomes 2,783 i.h.p., and the total water consumption for the 10 minutes comes out to 8,250lb. for Fig. 3.

ascertained from the consumption for each element of the load. The result is 7,220lb. for the 10 minutes for Fig. 3, as given in Table I.

In the fifth case — combined expansion governing and throttling—the consumption is given by the constant-pressure water-consumption curve down to 20lb. mean pressure, and for lighter loads by the Willans line marked W_4 in Fig. 6. The calculations are similar to those in the previous cases, and the results are given in Table I.

A comparison of all the results obtained, Table I., shows that the fifth arrangement is the best for all three typical load curves. On the mere question of economy of water evaporated it will be noticed that there is perhaps not so much difference between the first three arrangements as might be expected. The third arrangement has, however, the great advantage that only four engines are required. The advantages of expansion governing are striking: a considerable saving in feed water is effected, and two engines less are needed than in the first arrangement. In fact, this is just the case where expansion governing might almost be said to be a necessity.

LORD KELVIN AT WOLVERHAMPTON.

At the luncheon which followed the opening of the Wolverhampton central station, which we briefly described last week, Lord Kelvin delivered an address. In the course of his remarks he said that Wolverhampton had gained by being patient in the matter, and waiting for the best scheme, and the works he had just inaugurated had a particular interest for electricians, for he had always advocated high pressure when distant work had to be done. The works there were practically the third of their kind adopted in the country, for the system was first introduced in the Chelsea system, and then carried out by the Electric Construction Company in lighting the town and University of Oxford, the success of which work

Digitized by Google

was due to Mr. Thomas Parker. He hoped the Wolverhampton scheme would be a similar success. The Corporation had done well in taking the course they had, and were pioneers of progress in adopting the system he had mentioned for Wolverhampton. The method which had been adopted by the Wolverhampton Corporation had not had a very widely extended trial, but the trial had been sufficiently severe to prove it to be the best adapted for the purpose required, and he thought that the lighting bill, and machinery bill, and labour bill of the undertaking, and all other expenses, would compare favourably with the cost of similar undertakings in any other town in the United Kingdom. The direct-current transformer, which really originated with Mr. Thomas Parker, had been adopted, and it was perfectly well known as associated in a fundamental manner with the idea of the conveyance of electricity over long distances. Electricians did not seem to appreciate the possibility of obtaining dynamos for a voltage of as high as 20,000. A great many of them, indeed, said that they could not make a 20,000-volt direct-current dynamo, but he would guarantee that certain electrical engineers only wished that they could get an order for the manufacture of such a dynamo. The fact that a 2,000-volt dynamo for direct current was the highest that had been made was not a reason for believing that it could not be exceeded. He was quite sure, however, that it could be, if only by the method of placing 10 2,000-volt dynamos in series. In this way it would be perfectly easy to obtain a voltage of 20,000, even in the absence of dynamos capable of producing a voltage of more than 2,000. That method had also this advantage—that it very greatly reduced the possibility of a breakdown. They had present at that gathering in the persons of the contractors guarantees for the success of the undertaking. Messrs. Parker, Blackburn, and Callender were three great successful electrical engineers. He had been to the Town Hall and had seen the transforming system (which had worked so well at Oxford) in operation, and also a method of regulating the pressure which was almost entirely novel, having been only partially realised in Oxford. In Oxford, however, the current never exceeded 1,000 volts, whereas in Wolverhampton it could always be maintained at 2,000. The general principle of regulating the pressure which was adopted there was the work of the Electric Construction Company. The pressure was regulated at the Town Hall, where there were four transformers, and where the high-pressure current received from the generating station was reduced in voltage sufficiently for the purposes of consumers. Electricians would look with intense interest to the working result of the system, and it had already worked sufficiently to justify the boldness and the wisdom of the Corporation in adopting the system.

THE PROJECTED ELECTRIC TRAMWAY AT ACTON.

The Parliamentary Committee of the London County Council reported as follows to the latter on Tuesday concerning the provisional order of the London United Tramways Company, to which we referred last week:

This order is to authorise the construction of doublings and passing-places in King-street, Hammersmith, and of a short single line to connect the existing tramways in King-street and Beadon-road, and to construct other lines outside the county boundary. There is also provision in Clauses 10 to 22 for the use of electric or other mechanical powers, subject only under Clause 11 to the consent of the Board of Trade during any period not exceeding seven years, and Clause 20 expressly sanctions the use of overhead wires, and the placing of posts and brackets in the streets as may be necessary and proper for working the tramways by electric or other mechanical power. The Council on January 29 refused its consent to a proposal of the company to adopt a system of electric traction by means of overhead wires, and the Highways Committee is of opinion that this clause should be struck out of the Bill. Clause 7 empowers the company, with the consent of the Board of Trade, to vary the construction of lines authorised or laid, and Clause 9 sanctions the construction with the approval of the Hammersmith Vestry, of any passing-place which may be found desirable. The consent of the Council also should be necessary in these clauses, and in Clause 11 above referred to. The Highways Committee is of opinion that the Council may be advised to consent to the order being proceeded with upon the promoters giving an undertaking to insert a similar clause to Section 23 of the West Metropolitan Tramways Act, 1889, and also for providing for all new works under the order, and all renewals or reconstruction of existing lines to be carried out to the satisfaction of the Council within two years from the confirmation of the order, and that the time of purchase of all the tramways of the company within the county of London shall be 1909 instead of 1903; and if the works requisite for completing the lines and putting them in good working order to the satisfaction of the Council be not carried out within the two years above specified, the provisions of Section 23 of the Act of 1889 to apply to all the tramways of the company, including those to be authorised by the order; and that the order shall be amended by the insertion of such of the Council's standard clauses as the Council may require, the elimination of Clause 20, the amendment of Clauses 7 and 9 by the insertion of words making Council's consent a necessary preliminary to any works under those clauses and that the order shall be further amended as the Council may require. We recommend that the Council do consent to the order being proceeded with, subject to the above-named conditions.

NEXT WEEK'S NEWS TO-DAY.

The Welsh Land Commission met yesterday and took evidence on the subject of light railways.

The shareholders of the Waterloo and City Railway Company held their second half-yearly meeting yesterday, when the report was adopted. The report seemed satisfactory, and everybody seemed satisfied with it.

Mr. Bryce had given notice that he would, yesterday, ask for leave in the House of Commons to introduce a Bill to facilitate the construction of light railways in Great Britain. Yesterday in the House, on the motion of the Chancellor of the Exchequer, it was resolved that to-day the introduction of Bills should have precedence of the orders of the day.

The officers of the District Railway have been puzzled of late on account of the repeated forcing of the locks of the electric reading-lamps and the abstraction of the pennies. A sharp watch was kept, and an inspector caught Frank Trew, a boy of 14, with whom was a boy of 13 named Flint, forcing the lock with a penknife. Both boys were arrested, and charged at Westminster yesterday. The magistrate ordered Trew to pay the damage and 1s. fine, or be imprisoned for seven days. The younger prisoner would be remanded to the workhouse for a week.

Mr. Bryce, replying yesterday in the House of Commons to questions by Mr. Howard and Mr. Rowlands as to the recent explosions in Cannon-street, Southwark Bridge, and elsewhere, said the electric lighting regulations provided that all street boxes shall be efficiently protected against any contact with gas or water pipes, and the Board was earnestly pressing upon electric lighting companies the necessity for compliance with these regulations. It was desirable that gas companies also should take the best steps to remedy defects in their plant, and he was now calling their attention to the matter.

THE CANNON-STREET EXPLOSION.

The report of Major P. Cardew to the Board of Trade has been issued concerning the accident which occurred in the City on November 10, 1894, when a horse was killed and some persons suffered injury and received electric shock. Major Cardew deals at some length with the causes of the accident, and makes several recommendations, including the adoption of a system of natural or forced draught. Pressure on our space prevents publication of the report in the present issue. It may, however, be mentioned that the inspector states that the causes of the explosion were the breaking down of the insulation of a high-pressure main in the street box at the corner of Budge-row, leading to the formation of a powerful electric arc between the outer conductor of this main and the end of the iron pipe forming a conduit for the mains under Budge-row, which projected into this street box, and the consequent charging of this pipe to a dangerous extent, and the presence of gas in the electric light company's pipes and street boxes to an amount which formed a highly explosive mixture in the street box at Walbrook, where the more serious explosion occurred, the gas being fired by the electric arc.

Proposed International Exhibition.—Mr. G. Hayter Chubb suggests that a great international exhibition should be held in London in 1901.

EXPLOSIONS AND UNDERGROUND MAINS.

It was only a few weeks ago, as will be seen from our issue of January 11, that we discussed the question of mixtures of coal gas and air being ignited in connection with underground mains laid in conduits or pipes. Since then our columns have contained statements of the results emanating from the practical experience of, among others, gentlemen engaged in the most important electricity works in this country. A perusal of our present issue, and of those of the 25th ult. and 1st inst., is sufficiently convincing on this point. It shows four remarkable facts. First, that very little, if any, trouble has arisen through the accumulation of coal gas in conduits or boxes so as to form an explosive mixture with air and eventually result in an explosion. It demonstrates, secondly, that the consensus of opinion is that explosions can be prevented by the adoption of efficient means of ventilating the underground systems. Thirdly, that the use of armoured concentric cables laid direct in the ground renders practically unnecessary any consideration of the question of explosions, no such trouble being experienced in connection with this system. It demonstrates, fourthly, that the so-called danger of electrolytic action is a bogie which may be entirely dismissed from consideration at the present time.

Taking the four points *seriatim*, it is gratifying, on the one hand, to be able to record that in the majority of cases coal gas has not proved to be a bugbear in regard to central-station working; but at the same time it appears unfortunately to have recently come forward as a disturbing factor, and this danger has still to be dealt with—and obviated. Even during the past fortnight explosions have occurred in London, Dover, Rochester, and Eastbourne, as mentioned in another part of the present issue. In three of these cases it has been shown that the ignition of explosive mixtures of gas and air has not been brought about through the electric supply systems, although occurring in connection with the underground work; whilst in the fourth instance the explosion is attributed to sparking. Moreover, Major P. Cardew, whose report on the Euston-road explosions is given in another column, concludes that they were due to the firing of a mixture of coal gas and air by an electric spark, and he emphasises the importance of overcoming sparking and of providing efficient means of ventilation. Of course these constantly occurring explosions are alarming, and just in the same way as they can be prevented, so must they be avoided. As to the second point, there seems to be not the slightest doubt that this important question of preventing explosions has not been sufficiently considered by supply companies and corporations. With a properly designed underground system the possibility of the ignition of an explosive mixture of coal gas and air should never be present. It all depends upon what it is intended to use—whether ventilating pipes, grids, or the forcing of dry air under pressure throughout the whole of the system of conduits or pipes, or placing sandbags in the boxes and chambers. What

Digitized by Google

may be suitable for one town may be unsuitable in another. The third point scarcely needs any consideration. The boxes are so small that no one at the present day would dream of explosions in connection with them. As to the fourth, that has already been answered—the so-called difficulty is non-existent.

It is quite obvious that the explosions which have occurred never ought to have happened. It is also evident that if underground conduit and pipe systems had been originally designed with a view to meet possible contingencies in the future, such explosions would not have taken place, and they should not do so now. Someone is to blame for this neglect, and the difficulty is to locate the responsibility. Electric lighting companies and corporations were perfectly aware before laying electric light mains or cables of the saturation of the subsoil with coal gas. It was not a new thing to them, and their duty was to so design their systems that either sparking should not occur or that gas, at all events, in sufficient quantity so as to form an explosive mixture with air, should not reach any part of the system where sparking might occur. But as the condition of affairs in the majority of cases is that no such provision has been made in the laying of underground systems, the best must be made of existing circumstances. Ventilation in some form or other is absolutely essential, and some efficient system must be introduced to overcome the present difficulty, whilst the connections in the boxes must be so made that sparking is rendered impossible. The subject must be thoroughly thrashed out, and we would suggest that the Council of the Institution of Electrical Engineers should allow two or three evenings for the matter to be properly discussed.

TROP DE ZELE.

The ambitions—and efforts to attain them—which have been manifested continuously by the London County Council in the direction of municipal undertakings are of a most far-reaching and inclusive order, and the limits to operations or matters deemed to be of public interest are—if even decided at all—certainly put so wide as to be almost out of sight. With respect to such matters as the supply of gas, electric light, and water, or even the ownership, if not the operation, of tramway lines and other methods of rapid transit, opinion is, as we have frequently had occasion to point out, fairly unanimous in approving of these as proper objects for municipal undertakings, whether in London or elsewhere; but when we come to other matters—the proper development, for instance, of a telephone exchange system in any urban district—the question is not so readily decided in the affirmative.

It is confessedly difficult to draw any exact line between matters rightly concerning local authorities and those which should remain outside their range of action, and even the principles which might lead to a decision are by no means clearly enunciated. Is, for instance, a local authority to take up only such enterprises as it can profitably conduct, or must the broad question of public benefit alone decide upon municipal undertakings? Then comes the question as to what matters *are* actually of general public benefit. Artificial light and water supply are obviously needed by all: tramways and other means of rapid transit are required by the majority, and perhaps should be included. Can the same be said of telephones?

The London County Council (and many other municipal bodies, too) think that the urban telephone systems ought rightly to be in the hands of the municipalities, and this position was emphasised by the deputation from the Council which waited upon the Postmaster-General a few days ago with reference to the subject. We cannot help thinking that Mr. Arnold Morley took the proper line in this matter, and showed to the deputation that, whilst being far from hostile to municipal enterprise, the Government could hold out no great hope to local authorities of municipal telephone systems coming into existence for many long years, if, indeed, at all.

We have already had occasion to point out that the purchase and erection by the Government of trunk mains for telephone use over the country must prove to be the first step in the direction of eventual State control over the entire enterprise, just as with the telegraphs: and it is a very big first step, being practically halfway to the desired end. But at present, and whilst the National Telephone Company hold their license, there seems no prospect of successful competition on the part of any local authority in establishing a telephone exchange system. Technical considerations—the want of uniformity in systems used in different towns, etc., or the mere question of metallic returns alone—must prove formidable drawbacks to intercommunication between towns where one is in the hands of the National Company and the other operated by the local authority, even supposing that the former would be willing to accept messages brought over the Government trunk mains from outside their own domain. We do not attempt here to fully discuss the question of urban exchange work, for obviously this might be as advantageously carried on by the local authority as by the National Company, if the ratepayers consider it wisdom to spend large sums in buying or erecting a complete urban system which cannot fairly be of use to one-third or less of the inhabitants. The proportion in London alone is not more than 1 per cent. of the total number of householders, if, indeed, as much; and cheaper rates, coupled with better service, would not increase the list of subscribers so materially as to justify the enterprise becoming a municipal undertaking.

From both aspects of the case, therefore, we consider that the County Council failed to make out its case in this matter, either as regards the question of urban or inter-urban communication; and all that can be said is that it has shown "too much zeal"—has been premature and hasty in attempting to carry more on its shoulders than is right or advisable. Questions like that of telephonic communication require handling by the statesman accustomed to national affairs, rather than by the man of smaller views who perhaps does excellent work in parochial affairs.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTRIC BRAKE COUPLINGS.

SIR,—If Mr. Frank B. Lea will tell me in your next what he does not understand, I will try and explain the queries he does not understand. As to the connections he speaks of with the car axles, this I fail to understand. In air and vacuum systems there is a rubber pipe to give flexibility when turning round curves. This pipe is between the carriages, and Mr. Lea can see it if he goes to any of the railway termini. I meant the wires which convey the current to the magnet to apply the brake, like the Timmis-Forbes brake, for instance, which was tried about five years ago. Now, in electricity there would be wires running through the train, and perhaps I ought to have said joints—by this I mean where the wires connect together so that they can be connected or disconnected. In railway language, the rubber pipes are known as couplings. I don't know what other name to call them. What I meant by reliable was, could they be connected and disconnected easily, and when once connected would they come apart, and would there be excessive leakage; and if they did come apart, would it injure the wires or joints?

There is, of course, only one company of the name I spoke of. I don't see how there could be two, or else the Electric Traction Company would get an injunction against the new one to prevent it from using its name. The one I meant was in New Broad-street, but it has been wound up, also the General Electric Power and Traction Company, a reconstruction of the old one, has shared the same fate.

If Mr. Lea does not understand my queries, would he mind giving me his address, and he can have mine, as if I sent him a sketch he might be able to know what I mean. Perhaps he will tell me also where I can see a sketch of the jack-spring coupling he mentions.—Yours, etc.,

London, February 5, 1894. A. M. BUSHELL.

OBITUARY.

GEORGE E. PREECE.

We regret to announce the death of George E. Preece, who was born at Carnarvon in 1838, and died at Colwyn Bay on the 2nd inst., having nearly completed his fifty-seventh year. The deceased, who was the brother of Mr. W. H Preece, F.R.S., entered the service of the Electric Telegraph Company in 1854, and from 1856 to 1861 was attached to the repairing ship "Monarch." In the latter year he went to Malta in charge of the Mediterranean cables, which formed the commencing link of the present Eastern Telegraph Company's system. He was also employed in laying the cable from Florida to Havana in 1867-8. In 1869 George E. Preece was connected with the laying of the Persian Gulf cable, and was wrecked in the P. and O. steamer "Carnatic" in the Red Sea in September of that year. Subsequently he was employed upon the construction of the French, Atlantic, British-Indian, and Falmouth and Gibraltar cables; and also was in charge of the manufacture and submersion of the Jersey and Guernsey Company's cables. He joined the Post Office Telegraph Department at the transfer of the telegraphs to the State in 1870, but retired in 1878. He was secretary to the Society of Telegraph Engineers from 1872 to 1876, and his paper on "Underground Work," read before the society in 1873, was highly appreciated by the profession. In 1884 he joined the firm of Messrs. Walter T. Glover and Co., and died in the company's service. The deceased had been in failing health for some time, and was, in consequence, incapacitated from attending to his duties; but all through his illness he was ever ready and willing to give such information as he could to his fellow-officers. This was always valuable, in consequence of his long experience, especially in connection with the company's electrical testing department. The deceased, who was a frequent contributor to the technical journals, especially the *Electrical Review* and the *Mechanical World*, as well as to the Society of Telegraph Engineers, was interred at Manchester on Wednesday.

REVIEWS.

Lockwood's Builder's, Architect's, Contractor's, and Engineer's Price-Book for 1895. Edited by FRANCIS T. W. MILLER, A.R.I.B.A. London: Crosby Lockwood and Son. Price 4s.

To the electrical engineer there is little of interest in this price-book. There are some 30 pages devoted to electric lighting plant and accessories—and that is all. Consulting electrical engineers who are their own architects will, however, find much information of value, although the book, giving as it does the latest prices of materials and labour in trades connected with building, mostly appeals to builders, engineers, and contractors. A copy of the new Act relating to buildings in the Metropolis is given as a supplement.

THE MADAGASCAR CABLE.

In referring to the recent outburst of Anglophobia in the French Chamber, the Paris correspondent of the *Times* says: "When some months ago there was a talk of laying a cable to Madagascar, one of the leading English firms offered, under the most absolute conditions of security, to lay the cable before the date fixed for the departure of the expedition. The offer was refused, and the contract was given to the Construction Electrique de France at a much higher price—300,000f., I believe—and it will most likely not be laid in time. Such is the present strange and dangerous state of mind of Frenchmen."

In reference to the same subject, the chairman of the Eastern Telegraph Company is reported as informing his shareholders that proposals had been made by the company to the French Government to connect Madagascar with the present cables at Mozambique, but that the French Government did not avail themselves of this offer. Sir John Pender also points out that the company had always ships about with cable on board of them, and that if any hitch occurred in the work he should not be astonished if in this case, as in others, the company should eventually lay the Madagascar cable.

It is, however, possible that the coyness of the French Government may arise from the knowledge that the cables both north and south of Mozambique have been in a very unsatisfactory state for the last few months. According to official reports, we find that some of these cables between Durban and Aden have suffered interruptions amounting to a lump total of 148 days in a period of 118 days. It is true that these interruptions were concurrent, and that the cable which was interrupted for the longest time was duplicated; but such a state of affairs is in no way calculated to inspire confidence in the French Government, who, in any case, are doing all they can to protect and foster the manufacture of telegraph cables in their own country.

LIGHT RAILWAYS.

In our last issue we editorially summarised the report of the Committee of Conference on Light Railways. We now give below the memorandum signed by Messrs. W. J. Carruthers-Wain and Stephen Sellon and Sir Albert K. Rollit, M.P.

MEMORANDUM.

We regret we are unable to sign the report, and beg to give our views upon the questions submitted to the conference.

(1) The committee considered closely the present law as well as the Board of Trade and local regulations concerning tramways of the first magnitude, such evidence having occupied the attention of your committee for two sittings, and has been the subject of constant reference throughout their deliberations.

(2) To relieve the congested districts, to afford communication between urban and suburban districts, and also to provide facilities for the transit of passengers and goods from and to the great cities, large extensions of the existing tramway systems would be most advantageous, and naturally would not necessitate the purchase of valuable land, either for terminal stations or for carrying the lines through towns, and would, in addition, get rid of terminal charges and the construction of the most costly works of a railway—viz., tunnels, cuttings, embankments, viaducts or bridges, stations, and expensive

Digitized by Google

signalling and interlocking apparatus. In many cases such lines could be made at the sides of the roads, or on the waste land at the sides, thus avoiding any extensive interference with the public highways.

(3) It is to be regretted that the railway companies do not appear to have seen their way to have made any serious attempt to construct light railways as feeder lines. Had they so desired, special powers might have been obtained for the purpose without regard to the Light Railways Facilities Act, 1864, especially after the adoption by the Standing Orders Committee of the word "tramroad," a distinction made to enable light railways to be constructed under the Tramways Act with no statutory regulations as regards speed working unless they are laid on the public highways, in which case modified regulations under the Tramways Act apply. Parliamentary sanction has been given for the construction of several miles of this class of line, and they would have been made if the projectors had been possessed of the same advantages which railway companies have when promoting extensions of their own systems.

It is not generally understood that tramroads are entitled to the benefits of the Railway and Canal Traffic Acts, and can therefore insist on having working agreements with the neighbouring railways as if the tramroads were railways.

We consider that the lack of progress in the construction of tramroads or light railways as feeders has been due to the want of more generous treatment by railway companies, and as an example we refer to the Southwold case. It appears to us that such treatment would not have been detrimental to the interests of the railway companies.

(4) We think that the statement in the report as to the lack of progress, and the impediments to the construction and restrictions on working, does not sufficiently represent the actual facts, as it is well known that obstacles to the construction of tramroads and tramways have been unnecessarily interposed by the local authorities and the Board of Trade, notwithstanding that either of these bodies have the power to modify or relax many of their requirements.

We recommend that the Board of Trade should have full power to modify or dispense with any of the existing restrictions on the construction and working of tramways.

The absence of progress in this country is best illustrated by showing the mileage of secondary railways alone, not including tramways open for traffic in the following countries, from official information given to the committee :

	Miles.
France, 1893	2,250
Hungary, 1892	2,300
Germany, 1892	1,620
Italy, 1890	1,250
Belgium, 1893	770
Netherlands, 1894	160

(5) With regard to the expenses of promotion, we recommend that where county councils are themselves promoters of light railways, tramroads, or tramways no deposit should be necessary, and that where independent promoters seek to obtain similar powers, no deposit should be payable until the lines have been authorised and the work of construction about to be commenced, in which case a deposit should be made to the local authority; such deposit being returnable with interest *pro rata* on the completion of each section of line as may be agreed.

With a view to reducing the cost of promotion, we recommend that, instead of the present mode of procedure, it is desirable that Parliament should authorise the Board of Trade to sanction the construction of light railways, tramroads, or tramways which are approved by the county council concerned, and in cases where several county councils are interested the Board of Trade, after holding a local enquiry, should have power to overrule the objections of the minority.

(6) As under the present standing orders affecting tramroads and tramways one frontager has prevented Bills being considered on their merits, we recommend in all cases of opposition by frontagers that claims both as to opposition and compensation should not prevent a Bill or order being considered on its merits, and if the proposed line is shown to be of public utility, the opposition of such frontager or frontagers should be overruled.

(7) The committee considered the question of acquiring land by compulsory powers, and we recommend that the principle adopted by the Local Government Act of 1894, in regard to the compulsory acquisition of lands for certain purposes, should be extended so as to enable local authorities to purchase lands necessary for proposed lines.

We consider that it is contrary to the public interest to grant without the closest enquiry any powers for the compulsory acquisition of land by any railway, tramroad, or tramway company which is desirous of obtaining powers for the conveyance of goods and not of passengers.

(8) The committee have had abundant evidence to convince them that, except in isolated cases, it would be impossible, under existing conditions, to obtain from the public the financial support necessary to enable light railways, tramroads, or tramways to be economically constructed, and we feel, therefore, that having regard to the terms of the reference and to the speech of the President of the Board of Trade at the recent conference, it is our duty to state our opinion that, following the precedents in Belgium and other countries, that the county councils and other local authorities should be empowered to subscribe or guarantee capital, or interest on capital, for this purpose.

GAS EXPLOSIONS.

Southwark Bridge

A somewhat serious explosion took place early on Friday afternoon on Southwark Bridge, whereby five persons were injured. It appears that the explosion occurred in the four boxes near the centre of Southwark Bridge, on the east side. The force of the explosion blew up the pavement and wrecked the framework of the covers on the boxes, which were shot some distance into the air, and on the south-west end of the bridge a large hole was made in the pavement, close to a gully which is contiguous to some junction-boxes.

An enquiry into the cause of the explosion was held on Monday at the Guildhall by Major Cardew, on behalf of the Board of Trade. Mr. H. Homewood Crawford (City solicitor) appeared for the Corporation, the trustees of the Bridge House Estates, who own Southwark Bridge, and he also represented Lieutenant-Colonel H. Smith (commissioner of City Police). The City of London Electric Lighting Company, Limited, was represented by Mr. F. Bailey (chief engineer), and the South Metropolitan Gas Company, Limited, by Mr. Frank Livesey (chief engineer).

Police-Constable Sawyer said that on the day of the accident he was on the west side of Southwark Bridge, going north, when he heard an explosion behind him. As he was turning round another occurred. He saw three clouds of smoke rising and a man blown into the air several feet.

Miss Florence Heath, residing at South Hampstead, stated that when walking about half-way across the bridge from the City she saw a cloud of smoke on the west side at the south end, and heard a loud report. This was followed by another explosion just in front of her, with smoke, accompanied by the displacement of flagstones. When turning round she heard another explosion.

Several other witnesses gave corroborative evidence.

Police-Inspector Eve said that shortly after 2 p.m. on the day in question, he was on the bridge with officials of the electric lighting company. They went to the iron box lid at the south-east corner and lifted it. There was a strong smell of gas from the box, which contained a gas-meter. They then went to a similar box with a meter on the west side, where there was also a strong smell of gas.

Mr. W. Cupid, outdoor foreman to the South Metropolitan Gas Company, said about three o'clock on the afternoon of the accident he opened the road at the south-west corner of the bridge, and found a 3in. main cracked about half-way round and split lengthways about 6in. The crack was about the thickness of a sheet of a paper. It was centrally over a culvert which passed across the roadway. The main passed about an inch above the electric mains.

In reply to the **City Solicitor**, the **Witness** said the crack round the pipe might have been leaking two or three days, or it might have been caused by the explosion.

Mr. R. Thompson, in the service of the electric lighting company, said he last examined the boxes on the bridge on the 25th ult., and there was no smell of gas in them then.

Mr. J. P. Buck, superintendent of street work for the electric lighting company, said that when the explosion was reported to him he went to the bridge and found a strong smell of gas coming from the manhole and the gratings. The electric mains were uninjured except for a few dents caused by stones. Twelve men were constantly employed in searching for gas in the electric light boxes.

Mr. T. Blythe, foreman to Messrs. Mowlem and Co., said in January last his employers were engaged by the City architect to carry out the construction of new gullies on the bridge—one on the east side and one on the west side at the south end of the bridge. He cut away the brickwork from the old grating above the culvert and close to the gas pipe, but he did not touch it. The particular part of the pipe found cracked they did not go near. He thought the frost and rain might have caused the crack in the pipe owing to its being so close to the surface.

Mr. F. H. Jackson, in charge of the electric lighting company's plant, produced an automatic voltmeter record showing that at the time of the explosion there was no record of any disturbance at the company's works.

Mr. Livesey observed it was impossible to prevent all escapes of gas. They had many difficulties to contend with in connection with this matter. One of these was the heavy steam-rollers. Although their mains had to a great extent been placed deeper since these were brought into use, the company could not relay the whole of their mains, as that would mean taking up all the streets in South London. Then the sewers were laid underneath their mains, and pipes were sometimes broken in this way. He could not suggest any reason for the explosion. Generally, when there was an accident of the kind they were able to trace a light to somewhere, but in this case they were unable to do so.

The proceedings then terminated.

Digitized by Google

DOVER.

The explosion which occurred at Dover on Thursday of last week, as reported in our last issue, took place whilst an employé was working in one of the manholes at the lower end of Snargate-street. The man was using at the time a flare lamp, when an explosion occurred of some gas which had accumulated in the next manhole below, and blew off the cover of the manhole, but did no injury to anyone. The draught had blown the gas up the pipe which connects the two manholes, and had been ignited by the workman's lamp, the lamp being blown out of the man's hand. As stated last week, the explosion was not due to any sparking, as the current has not yet been switched on to the mains. Moreover, it is intended to endeavour to prevent explosions when the company set to work by filling the boxes with bags of sand and providing the transformer-chambers with ventilating gratings.

ROCHESTER.

In the town of Rochester, which was the scene of an explosion the previous week, another explosion took place on Saturday in a chamber beneath the pavement. It occurred at the same spot as the previous explosion, and apparently from a similar cause—namely, an escape of coal gas coming into contact with an electric spark. Another explosion is reported to have occurred on Wednesday evening

EASTBOURNE.

An explosion occurred on the 25th ult. near the junction of Terminus and Cornfield roads. One of the workmen of the Eastbourne Electric Light Company was engaged in testing a piece of cable between two boxes. A jointer, who was assisting him, was using a spirit lamp at a box, when there was an explosion of gas, which blew off the tops of three boxes on the other side of Terminus-road. A black smoke rose from the box for a few seconds, and there was a strong smell of gas, plainly indicating the cause of the explosion, which was not in any way due to the electricity, as the engines were not running at the time. This is the first accident which has taken place in Eastbourne during the time the electric light company has been at work.

THE GOVERNMENT AND TELEPHONY.

The deputation from the London County Council which had an interview on Monday with the Postmaster-General at the General Post Office on the subject of the telephone service of London, very properly received a direct snub. The deputation, which was introduced by Mr. Benn, M.P., consisted of Mr. Dickinson, Mr. Edwin Jones (the chairman of the Telephone Committee of the Council), Mr. N. W. Hubbard, and Mr. J. Thornton. The Postmaster-General was accompanied by Sir Robert Hunter, Mr. Spencer Walpole, and Mr. J. C. Lamb.

Mr. J. W. Benn, who introduced the deputation, said that what the Council desired was that a committee should be appointed to consider the case of London in the matter of telephones.

Mr. W. Dickinson, the deputy-chairman of the Council, said at present the National Telephone Company had a monopoly which rendered competition almost impossible, and they suggested that restrictions should be imposed, or that the Government should take over the direction of the telephones, or that they should be given over to the County Council. He argued that the maximum cost of a telephone for the year should not be more than £10, and further asked that a committee might be appointed, so that the whole matter could be threshed out, as at present the terms of the agreement were such as to render it impossible for competitors to carry on business. The agreement afforded such facilities to the National Telephone Company as practically placed it in a most advantageous position to carry on its business and increase its profits. The Council said if that was so, there ought to be conditions which would limit the charges and profits of a company which enjoyed a monopoly.

The **Postmaster-General**, in reply, pointed out that it was asked that the Government should go back, not only upon a policy approved by Parliament in 1892, but upon an agreement which was actually signed by the Government of the day with the two telephone companies. What they were proposing to do under this agreement was for the State to take over a great portion of the telephone work from the telephone company. That was to say, the taking over the whole of the trunk system, and by this agreement they were making a long stride in the direction of the telephone system passing under the control of the State. The Government were carefully considering the whole question, but after the experience in 1870 in connection with the telegraphs, they needed to give the matter the most serious consideration before they decided to compulsorily purchase. Nothing could be more detrimental than a competing system. No monopoly had been given to the National Telephone Company. If they failed to provide a reasonably efficient service, the Post Office had the right to set up a telephone, or of granting another body a license to carry on a competitive system, but, speaking generally, he was confident that a competing system was a bad arrangement for an effective telephone system in any given area. The telephone was a luxury for the commercial and wealthy classes. They could not make it an ordinary means of communication for the great masses of the community, and he doubted the wisdom of any municipality taking it up. With regard to London, he was prepared to state that after these agreements were ratified London would be practically in the same position that it was before. They had safeguarded the position of local authorities by words which were amply sufficient to prevent anything being done without the previous consent of the County Council. The Government was perfectly free to carry on the telephone system itself or to give powers to other authorities.

THE RECENT EXPLOSIONS IN ST. PANCRAS.

BOARD OF TRADE REPORT.

We give below the report, which is dated January 18, 1895, of Major P. Cardew to the Board of Trade concerning the enquiry which he held into the circumstances connected with two explosions which took place in the electric light conduits in Euston-road on December 29 last :

I have the honour to report that, in accordance with your instructions, I held an enquiry on the 10th inst. as detailed above. The enquiry was held in the St. Pancras Vestry Hall. Prof. Robinson, the consulting engineer to the Vestry of St. Pancras, represented the Vestry, who are the owners of the electric light conduits. Mr. Bassett Hopkins and Mr. Gunyon represented the London County Council, and Mr. Foulger, engineer to the Gaslight and Coke Company, represented his company. I attach a transcript of the shorthand writer's notes of the evidence given at the enquiry. I also append to this report a return, furnished by the metropolitan police, of previous explosions which have occurred in connection with the system of electric lighting mains laid down by the St. Pancras Vestry

The supply of electrical energy for lighting and other purposes in this district is provided by the St. Pancras Vestry, who are the undertakers under the St. Pancras Electric Lighting Order, 1883. The greater portion of their system of mains consists of bare copper strip, supported on porcelain insulators, fixed about 6ft. apart with intermediate distance-pieces, in a conduit which in general is constructed of brickwork and cement concrete; but in portions at road crossings, or at places where sufficient depth is not obtainable to suit this construction, the conduit is formed by means of a cast-iron pipe 8in. in diameter. At intervals, which vary according to the requirements of the locality, street boxes or chambers have been made giving access to the mains for purposes of jointing, testing, etc. These are formed of brickwork in cement, and are closed in the usual way with an iron cover filled in with York stone. These street boxes are generally of considerable internal capacity and allow of a man getting into them to effect cross connections or other operations on the mains. The mains are laid on the three-wire system, and consist of a positive, a negative, and an intermediate main, the pressure between the positive and negative mains being rather over 200, and that between either and the intermediate main rather over 100 volts.

General Account of Explosions.

It appears that at 12 midnight on the 29th ult., Police-constable James Diprose, 436 D, was on duty at the corner of Gower-place and Endsleigh-gardens, and heard the report of an explosion in the direction of the Euston-road. Immediately afterwards a second explosion occurred at the corner of Endsleigh-gardens and Euston road, which he witnessed, and he saw the cover of the street box at this corner projected about 20ft. into the air. This cover was afterwards found to have been broken. A few yards to the westward, along the Euston-road, he found the cover of another street box displaced about 8ft., and beyond this again, for a distance of 30 yards, the pavement had been raised over the electric conduit by about 2in. Two men, Charles Govier and David Petrie, sustained injury by these explosions. The former attended the enquiry, and stated that they were walking together along the Euston-road when the first explosion took place: he saw a flash in the ground, was hurled into the air, and came down on his back. He struggled to his knees, when the ground heaved up, probably from the effect of the second explosion, and he was thrown into the gutter On getting to his feet he found Petrie in a dazed condition, clinging to the railings. They were assisted to the University Hospital where their injuries were attended to, and they were able to leave in a short time. The house surgeon's report was stated to be to the effect that Govier had sustained a bruise in his side, and Petrie a sprained ankle—both mild cases.

According to the evidence of Mr. Baron, the chief engineer and manager of the St. Pancras electric lighting station, and from my own inspection, I find that the street boxes in which the explosions occurred were numbered 26A and 27. They are about 10 yards apart, and the conduit between them is an 8in. iron pipe. The upheaval of pavement took place west of No. 26A, where the brickwork and cement conduit is in use. No external disturbance was apparent above the iron pipe. I had the whole length of this pipe exposed to view, as it appeared to me that possibly electrolytic action might have been in progress from a connection between one of the mains and this short length of pipe, and that this might have damaged service pipes or mains of gas or water in immediate proximity. There was, however, no trace of any such action. The brickwork conduit had been seriously damaged, the top being mostly shattered, and the bottom cracked to a considerable extent. The length of the portion so damaged is about 30 yards. The whole of this was opened up, and I closely inspected the conductors, but could not discover any sign of electrolytic action or of any electric arc or short circuit having taken place. In fact, these conductors are practically in as good condition as when first laid.

At several of the insulators, more especially in the street boxes, there was an incrustation of a saline material in the vicinity of the

Digitized by Google

negative conductor; this was distinctly damp, and no doubt would cause in the aggregate a serious leak. The tendency to the formation of this incrustation in the case of bare conductors used for electric lighting currents has been observed in several previous cases. The insulation resistance of this section of the mains was taken by Mr Thomas, the outdoor inspector, the day after the explosion, and was found to be only 330 ohms for the negative and 110 ohms for the intermediate mains in a short length of about 100 yards. That such a very low insulation as this is not an exceptional case on this system of mains is evident from a copy of a report on some tests of mains handed to me by the chief engineer, by which it appears that in May and June last year the insulation of the negative main in sections in or about the Euston-road was found as low as 150, and even 80 ohms, while in other parts very low insulation of this main was found, in one case only 40 ohms.

The chief engineer stated that he smelt coal gas immediately after the explosions in street box No. 27, in which the second explosion took place. Mr. Thomas, the outdoor inspector, stated that he smelt a strong smell of gas in a neighbouring street box, No. 26, on the 30th ult., and also on the 31st ult., when he drew the attention of Mr. Gunyon, engineer to the London County Council, to the smell, who also perceived it. Edwin Benyon, an electrical jointer in the employ of the Vestry, also smelt gas in No. 26 immediately after the explosion.

It appears that the street boxes are systematically examined for the presence of water or gas at intervals of from four to six days, and that gas was reported in No. 27 on the 13th ult. On the other hand, both No. 26A and No. 27 had been examined on the 28th ult., probably about 36 hours before the explosions took place, and were found free from gas, and Mr. Foulger, the engineer to the Gaslight and Coke Company, stated that the tests made by his company since the explosion had failed to indicate any leakage of gas in the neighbourhood, nor could I detect any smell on the 31st ult. or on the day of the enquiry. Since the enquiry, however, Mr. Foulger has informed me that a 4in. main was found to be leaking on the 9th inst. near the entrance to the London and North-Western Railway, Euston-square, and from information received from the Vestry it appears that the position of this leak was about 80 yards from the electric light conduit. The electric lighting officials admit that they frequently discover accumulations of gas in their street boxes, and the returns furnished by the police gives particulars of six explosions, all of which were probably caused by the firing of an explosive mixture of gas and air in connection with the electric lighting mains in St. Pancras.

It has been suggested that in the particular case now under consideration the explosive gas was derived from the sewers, but I do not think this at all a probable explanation. Mr. Foulger suggested at the enquiry that the gas might have been hydrogen generated by electrolytic action. This is certainly a more tenable proposition, and I took care to examine the conduits and conductors for any material evidence which might support it. No trace of such action was, however, discoverable.

After careful consideration of the evidence and of my own investigations, I am of opinion that the explosions were caused by the firing of a mixture of coal gas and air by an electric spark. I account for the presence of the coal gas by leakage from the mains of the Gaslight and Coke Company at one or more points in the vicinity of the electric light conduits; percolation of the escaped gas along the lines of gas and electric mains, which are parallel and in close proximity, where the soil has been frequently disturbed; and entry into the electric conduits and boxes, wherever small openings may exist, which from the construction and materials used will certainly be the case at many points. The gas would naturally percolate into the open space provided by the electric light conduit, and this would be facilitated to some extent by the small amount of heat produced by the electric current in the mains. It is probable that since the general adoption of wood pavement, and other forms of pavement which prevent the escape of gas from the soil directly into the open air, the danger of its percolating into underground chambers has been materially increased. The means provided by the Vestry for the immediate escape of any gas from their conduits are in my opinion totally inadequate, and even a slight leakage of gas into the conduits would be likely to accumulate until the proportion of gas in the air reached that necessary to form an explosive mixture.

The occurrence of an electric spark was, I think, probably a result of the formation of the salt incrustation on the insulators as mentioned above. This, no doubt, acts to some extent as a conductor, and if a piece break away, a small spark would very likely be caused. There are many other ways in which an electric spark might have originated, especially with this system of mains, but from my examination I think the cause suggested above the most probable. It is true that at about the time of the explosions the electrician on duty at the generating station observed a momentary fall of pressure, which probably indicated a sudden rush of current lasting for a very short time, but I am inclined to consider this occurrence as an effect rather than a cause of the explosions, since I could find no trace of any electric arc. It is possible that the intensely heated gases of the explosions may have allowed of the passage of a considerable current, and a number of partially conducting bridges of solid materials may also have been formed during the progress of the explosion connecting the oppositely-charged mains

The Vestry of St. Pancras should lose no time in removing the two existing causes of danger which I have indicated above—viz., the possibility of an accumulation of coal gas in their conduits, and that of the occurrence of an electric spark at their bare conductor mains. This system of mains and conduits was selected, I believe, mainly for economical reasons, and no doubt it has advantages in this respect, but these economical advantages must not be reaped at the expense of the safety of the public using the streets.

The Vestry were, I understand, advised by Prof. Robinson after the serious explosion which occurred on January 12, 1894, in a street box in Endsleigh-gardens, close to the position of the recent explosions, to carry out a system of efficient ventilation wherever possible and in a report on this accident, which was forwarded to the Vestry by the Board of Trade, I also advised this; and further recommended that, where possible, two small chambers should be substituted for the large ones at present in use as street boxes, and that the low insulation of the negative main, which was then, as now, a very noticeable defect, should be remedied.

Sufficient attention has not, I consider, been paid by the Vestry to these recommendations. It was stated by Mr. Baron at the enquiry that there are only 11 ventilating-pipes and three ventilating-covers to street boxes for a total length of 6½ miles of conduit, and the nearest ventilating-pipe was about 300 yards from the scene of the explosion. None of the large street boxes have, it appears, been divided into two smaller ones, as suggested by me, and the attempts made to remedy the serious leakage on the negative main have not so far been successful.

I am of opinion that the Vestry should immediately provide a thorough system of ventilation, or means for the immediate escape of gas from their conduits and street boxes, should reduce the empty space available for accumulation of gas in their street boxes as far as possible, and should carefully guard against the dangerous formation of an incrustation of salts on the insulators of the negative main by frequent inspection and by protecting these insulators against drip from the condensation of moisture on the iron lids of the street boxes.

RETURN giving particulars of all cases of explosions known to police which have occurred in the street boxes and culverts within the St. Pancras district since January 1, 1890:

Division D, November 10, 1894, 5.50 a.m., Tottenham Court-road.—The plate of a manhole, belonging to the St. Pancras Vestry, was broken, probably caused by being forced out of the aperture by foul air.

Division E, January 12, 1894, 5.10 a.m., Endsleigh-gardens and Euston-road (corner of).—The cover of a manhole, belonging to the St. Pancras Vestry, was blown out by an escape of gas, which exploded with a loud report. No personal injury.

Division S, December 28, 1892, 10.30 a.m., Cumberland-terrace.—Iron covers of culverts, belonging to the St. Pancras Vestry, were blown out by an accumulation of gas in the culvert.

Division S, December 29, 1892. 12.20 a.m., Cambridge-place.—Iron covers of culvert, belonging to the St. Pancras Vestry, blown out by an accumulation of gas in the culvert.

Division S, January 24, 1893, 4.59 p.m., Euston-road (near George-street), and Euston-road (near Melton-street).—Switchdoor to electric light post, belonging to the St. Pancras Vestry, blown off its hinges and shattered by an accumulation of gas in the culvert.

Division D, December 20, 1894, 12 night, Endsleigh-gardens and Euston-road, corner of.—Two iron plates to manholes, belonging to St. Pancras Vestry, blown out, supposed by an accumulation of escaped coal gas in electric channel. Two persons slightly injured and flagstones displaced about 440 yards.

LEGAL INTELLIGENCE.

FARMER v. THE WATERLOO AND CITY RAILWAY COMPANY.

This case was heard on Friday before Mr. Justice Kekewich in the Chancery Division of the High Court of Justice.

The case raised a question of very great importance to owners of property in the Metropolis—namely, whether the numerous companies now being projected for constructing underground railways are entitled, under what appears to be a common form clause now introduced into underground railway Acts, to tunnel through the subsoil under houses without being required to purchase the land and houses above. In the present case the defendant company were incorporated by the Waterloo and City Railway Act, 1893 (which incorporated the Lands Clauses Consolidation Act, 1845), for the purpose of constructing an underground railway from the neighbourhood of Waterloo Station to Mansion House-street, City, and by Section 5 they were empowered to "enter upon, take, and use" such of the lands described in the deposited plans and books of reference as might be required for that purpose. Under Section 7 the mode of construction was required to be by tunnels, and by Section 7 the motive power for the traffic was to be either electricity or cable traction. Then Section 36 provided that all persons empowered by the Lands Clauses Consolidation Act, 1845, to convey lands might grant easements. By Section 84 landowners might be required to sell parts only of lands and buildings. Then Section 85 enacted as follows: "With respect to the lands described in the second schedule to this Act which the company are by the provisions of this Act authorised to enter on, take, and use for the purposes of the railway and works, the company shall not be required wholly to take those lands, or any part of the surface thereof, or any houses, buildings, manufactories, and premises therein, or any cellar, vault, or other construction held or connected therewith, but the Company may appropriate and use the subsoil and under-surface of any such lands; and if the company require to take, use, pull down, or open any such vault, cellar, or arches as aforesaid, they may purchase, take,

Digitized by Google

and use, and the owners of and other persons interested in any such vault, cellar. or arches shall sell the same for the purposes of the railway and works, and the purchase of any such cellar, vault, or construction shall not in any case be deemed the purchase of a part of a house or other building or manufactory within the said Section 92 of the Lands Clauses Consolidation Act, 1845. But nothing in this section contained, nor any dealing with the lands in pursuance of this section, shall relieve the company from the liability to compensation under the sixty-eighth section of the Lands Clauses Consolidation Act, 1845, and every case of compensation to be ascertained under this Act shall be ascertained according to the provisions contained in the Lands Clauses Consolidation Acts." The object of this section was to create an exception to the general law that an owner of land is entitled not only to the surface, but down "to the centre of the earth," as well as "*usque ad cælum*," and therefore cannot be compelled to sell any part of a vertical stratum of his land without being paid for the entire stratum ; and also partially to repeal the law as laid down by the Lands Clauses Consolidation Act, 1845, and the numerous decisions upon it, that a railway company requiring to take land having a house upon it is bound to take and purchase not only the land, both surface and subsoil, but the house upon it and every part of the house. The second schedule referred to in Section 85 described "lands, etc , in respect of which easements only may be taken," the "lands, etc.," being lands and the houses on them situate in the parish of Christchurch, Southwark, and some of which belonged to the plaintiff as tenant for life. In July last the plaintiff received from the company a notice that they required to "appropriate and use" the subsoil under his property as shown on the accompanying plan, and at a depth not less than there indicated. The plan showed that the company proposed to construct their tunnel at a considerable depth below the cellars of the houses above. Beyond this notice the company had not served any notice to treat or paid or deposited any compensation, or given a bond, as provided by Section 85 of the Lands Clauses Act. The company having recently commenced borings under the plaintiff's land for the purpose of constructing their tunnel, the plaintiff commenced this action, and now moved for an interim injunction to restrain the company from entering upon or under the premises described in the notice, or any other property in the said parish of Christchurch, Southwark, belonging to him until the company had complied with the provisions of the Lands Clauses Act and the special Act.

Mr. Channell, Q.C., and **Mr. Methold**, for the plaintiff, contended that the word "appropriate" in Section 85 of the special Act did not mean appropriate without payment, and that so to construe the section would be contrary to every principle upon which railway Acts were passed. The company were bound under the Lands Clauses Act to buy the necessary vertical slice of the plaintiff's land before they could use any part of the subsoil for their tunnel.

Mr. Cripps, Q.C., and **Mr. Ingle Joyce**, for the defendant company, contended that Section 85 of the special Act had introduced a new procedure applicable to such cases as the present, and intended to supersede the cumbrous machinery of the Lands Clauses Act, while protecting the landowner; that the tunnel would be at a great depth, so that the injury (if any) caused by it would be merely nominal. If, however, any injury should result to the plaintiff, he could obtain compensation under Section 68 of the Lands Clauses Act. So that the company might take the subsoil under their special Act, and leave the plaintiff to compensation under that section.

Mr. Justice Kekewich said that provisions drafted by way of exceptions on such a code as the Lands Clauses Act were certain to give rise to difficulties which could not ordinarily be settled without more than one decision. But upon the present case his Lordship confessed he felt no doubt whatever. The defendants, the railway company, were incorporated by a special Act in the usual way, which Act incorporated the Lands Clauses Act. They were authorised to take certain lands, including lands of which a lateral stratum only was required by them in the present instance. Instead of leaving the rights of the company and the landowner to the operation of the Lands Clauses Act, it seemed good to the Legislature to introduce into the special Act a special provision ; but his Lordship thought that this special provision must have reference to the general provisions which were none the less applicable because of the special provision. This special provision was comprised in Section 85 of the company's Act, which began thus : "With respect to the lands described in the second schedule to this Act which the company are by the provisions of this Act authorised to enter on, take, and use for the purposes of the railway and works." Stopping there, that was the ordinary form of language in an Act of this kind. If the company desired to enter upon any part of these lands in the ordinary way they must proceed in the ordinary way, by notice to treat, to be followed by agreement or otherwise. But the section went on to say that the company were to be entitled for their benefit not to take the lands in that way, notwithstanding that they required to use those lands for the purposes of their undertaking. The section said, "the company shall not be required wholly to take those lands or any part of the surface thereof, or any houses, buildings, manufactories, and premises therein, or any cellar, vault, or other construction held or connected therewith." All those exceptions were directed to the provisions of the Lands Clauses Act which were well known, and to which, therefore, his Lordship did not intend to refer, and to the decisions which had construed those provisions. In this section there were no provisions as to what the company were to do if they did less than "take and use." Mr. Cripps said that this was a question of procedure. As at present advised, his Lordship was of opinion that the procedure was precisely the same whether the company entered on and took and used the lands, or whether they took any part of the lands, which they could not do but for the provisions of this section. He was of opinion that the provisions of the Lands Clauses Act must be treated as incorporated into the special Act for the one purpose quite as much as for the other. But this was only one point made by Mr. Cripps. The section went on to say, "the company may appropriate and use the subsoil and under-surface of any such lands." It was unnecessary to refer to the next clause, as to vaults, cellars. and arches. Independently of that special provision it was quite clear that the company could not take any part of the subsoil and under-surface from an unwilling landowner. He might say, "The land is mine from the centre of the earth to the heaven, and if you take any part of the subsoil you must take the whole of the land." In consequence of that right of the landowner this modification of the law was here introduced. The question was, What was the meaning of the words "appropriate and use?" Without referring to the definition of the word "appropriate" in the "Century Dictionary," his Lordship found, what was still better, a definition of it in Metropolitan Railway Company *v.* Fowler. It was defined by Lord Watson as follows: "To appropriate, according to its natural meaning, is to take and keep a thing by exclusive right; and, as I construe their Act, the authority which it confers upon the company is to take and exclusively possess as much of the subsoil below highways as may be required for the purposes of the undertaking." And it would be observed that the House of Lords held that what the company took in that case was "land." In taking so much of the subsoil they required, they excluded all other persons and made it their own. There was no possibility of reverter ; it was to belong to the company exclusively. Leaving the question of procedure, his Lordship would apply the much earlier principle of law that no one was allowed to take another man's property, notwithstanding it might be required for the general purposes of a public undertaking, without paying for it. Then Mr. Cripps said that the plaintiff might be "injuriously affected" within the meaning of the Lands Clauses Act, so as to entitle him to compensation under Section 68. That section covered purchase-money, and was therefore directly applicable to a case of this kind Unless the Legislature had distinctly said that the company might take the subsoil without paying for it, they could not be allowed to do so. On both these grounds his Lordship was of opinion that the company could not be allowed in any way to deal with this property except upon the terms of their paying a sum into Court. Then arose a question whether the word "appropriate" came within the "possession" clauses in the Lands Clauses Act. As at present advised, his Lordship thought it did, though he would not now pronounce an actual decision upon it; but perhaps the parties might not think it worth while to discuss that question. Upon the whole his Lordship held that the plaintiff was entitled to an injunction.

As the parties consented to treat the hearing of the motion as the trial of the action,

His **Lordship** made a declaration that the defendant company was not entitled to appropriate and use the subsoil under the plaintiff's property, or any part thereof, until they had complied with the provisions of the Lands Clauses Consolidation Act, 1845, in reference to the compulsory purchase of land. The defendant company to pay the costs of the action.—*The Times.*

COMPANIES' MEETINGS.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED.

An extraordinary general meeting of this Company took place on Tuesday at the Cannon-street Hotel, Mr. J. S. Forbes being in the chair.

The **Chairman** moved resolutions making certain alterations in Clauses 10, 11, 16, 20, 41, 41A, 59, and 65 of the articles of association. (We gave these proposed changes in full in our "Business Notes" on January 25.) The Chairman stated that the alterations were required in order to meet the wishes of the Stock Exchange before granting the Company a quotation. He went into the details of the various alterations in the clauses which were required by the Stock Exchange, explaining their effects.

The resolutions having been seconded by **Major Flood-Page**, they were put *seriatim*, and carried unanimously.

The **Chairman** pointed out that one of the principal advantages they expected to secure by the fusion of the two companies was that they might get a quotation on the Stock Exchange for the various classes of shares. They had a quotation for their Swan ordinary shares, but not for the fully-paid. In the Edison Company they had no quotation for either class of shares. He thought, however, that under the resolutions which had now been passed they would get a quotation for all their ordinary shares in the Edison and Swan. They had now emerged from protection into the free air of competition. He thought, however, he might state generally that the consequences of competition were not so disastrous to them as many people predicted would be. The Company had succeeded in establishing for its business a certain reputation. The trade mark of Edison and Swan still had its magic influence. They turned out a good article, and although they had been obliged to descend to the arena as regards price, he did not think that when the results of the first year's working were submitted to the proprietors they would find they had cause to be greatly depressed.

Digitized by Google

YORKSHIRE HOUSE-TO-HOUSE ELECTRICITY COMPANY.

An ordinary general meeting of the shareholders of this Company was held on Tuesday at Leeds. Mr. Grosvenor Talbot occupied the chair.

The **Chairman**, in moving the adoption of the report and statement of accounts, which were given in our issue of last week, said the directors felt that there was a certain amount of satisfaction in appearing before the shareholders. They had been able to earn a dividend of 4 per cent., and in addition to the dividend they had also earned almost an equal amount, which they were applying to other purposes. He believed that the result of the last year's working, which was the first complete year of their Company, was equal to the result of almost any country station in England. Their customers had full confidence in the Company, and almost all the new buildings which were being erected, or which had recently been erected, in Leeds were dependent entirely upon the electric light as an illuminant. On December 31, 1893, as the result of eight months' working, they had installed what was equal to 10,647 8-c.p. lamps. At the close of last year they had 19,858 lamps installed. They delivered, in units, in the eight months of 1893, 125,000; and in the 12 months of 1894 they delivered 291,113—that was to say, in 1893 they delivered 15 620 units per month, and in 1894 24,260 units per month. That statement of the amount per month might be a little misleading without explanation. In 1893 there were four good months in which they were not working, and therefore the comparison was rather too favourable for last year's working, but the increase was eminently satisfactory. They had now, in immediate prospect, the whole of the lighting of the Leeds Town Hall and Municipal Buildings, equal to about 6,000 8-c.p. lamps. They had also offered to the Corporation to light every portion of the streets or markets which they chose with arc lamps. Messrs. Fowler had agreed to take their 100 h.p. engine, and to replace it with a 400 h.p. engine, and that was now about to be done. As to the future, the directors felt that the price of the current was one of the great objects which they had to deal with, and they felt sure that by reducing the price they would immensely increase the sale. They had decided that from July 1 next the maximum price should be reduced from 7d. to 6d. per unit. They proposed some time during the next spring to extend their mains.

Mr. R. W. Eddison seconded the resolution, which was adopted.

Mr. J. T. Pearson (Melmerby) and Mr. R. W. Eddison, the retiring directors, were re-elected; and Mr. John Gordon, jun., was also re-elected as auditor.

CITY AND SOUTH LONDON RAILWAY COMPANY.

The ordinary general meeting of the City and South London Railway took place on Friday last at Winchester House, Old Broad-street, E.C. Mr. Charles G. Mott, the chairman, presided.

The **Chairman**, in moving the adoption of the report and accounts, which we published in our last issue, stated that he thought the shareholders would agree that during the past half-year the line had made, on the whole, very satisfactory progress. During that time the ordinary passengers, exclusive of season tickets, had increased by 182,298 over the corresponding period of the previous year. That was a considerable increase of the traffic of the line. They were aware that in the early stages of this line they had a very great deal of prejudice to overcome. Year by year it had been the endeavour of the Board to get rid of this prejudice. He was glad to say that, although it had not disappeared, it had immensely diminished, because they had been able to show that the line was perfectly safe, that it was a comfortable mode of conveyance, that it was absolutely punctual, that the lifts were perfectly safe, and that there was no danger whatever from the electric current. One of the most important questions, and one of the most anxious with them, had always been the question of the lifts. These involved constant and careful watching. The fact that those lifts had gone up and down 2,500,000 times without the slightest accident, or any difficulty of any kind, reflected the greatest credit upon those who had them in charge. In regard to the question of the traffic on a line of this kind, one of the greatest advantages of electric traction over locomotive machinery was that in working it there was very little wear and tear. Many of their locomotives had already run some 150,000 miles each, and were very little worse than when they started. That would show them one of the advantages which they would derive in future from the electric working of the railway. Referring to the accounts, he said that they had paid off debenture bonds £9,100, as well as a loan of £1,000. Those debenture bonds had been substituted for debenture stock, which had been issued at a little over 3 per cent. In addition to that, they had issued £4,100 of preference shares and £2,841 debenture stock, and they had received in premiums on the issue of the debenture stock £3,038, making a total of £10,179. They had expended during the half-year £2,936 upon rolling-stock and the new motor-car trains. Out of the balance of £7,783 they had increased the balance at the bankers by £5,850, they had paid off the loan of £1,000, and they had reduced their outstanding accounts by £1,574, thus more than accounting for the capital raised. They had provided the increase at their bankers for the purpose of paying off those debentures. The capital was reduced by the transference of the construction reserve which had been standing in the books for some time, so that practically this account stood at an increase of only a few hundred pounds for the half-year. The receipts from passengers showed an increase of £1,332, and the season tickets an increase of £140. The parcels showed an improvement of £24. On the other hand, there was a decrease in the rents received of £51, and in the sundry receipts of £27, leaving the net increase at £1,431. In the expenditure there were the following decreases: maintenance, £37; locomotive department, £23; traffic expenses, £43; carriage repairs, £73; and law charges, £73. In the result, there was an available balance in the revenue account of £10,919, and the dividend they recommended was double the amount they paid in the corresponding period of 1893. Their working expenses were reduced from 64·6 per cent. to 60·9 per cent., and deducting the cost of working the lifts, the percentage was reduced to about 51 per cent. The locomotive expenses per train mile had now come down to 6d. from 6·22d. The number of trains run during the half-year had been 73 208 against 71.143, an increase of 2,065, and the train miles were 230,604, against 224,101. Despite this increased train mileage, the receipts per train mile had been increased from 2s. 0½d. to 2s 1½d., and the receipts per passenger from 1·66d. to 1·77d. It was absolutely necessary to provide accommodation for their customers. They had done everything they could to increase the number of trains, but now, under the regulations of the Board of the Trade and under the peculiar circumstances of having a terminal station with only one line of rails, and with two lines of rails converging into it, they could not see their way to increase the number of trains run. Then the question arose, could they increase the size of the train? With that view they had been endeavouring to get rid of the locomotive and put another carriage on their train. After many experiments, they had at last got such a train successfully completed. The Board of Trade officers had approved it, with slight alterations, and it would be brought into running in the course of a few days, in order to be tested with passengers. The advantage would be that they would get another carriage. Except the King William-street Station, all their stations were capable of taking much longer trains, and two or three times as many as they now ran. It was a pity to see a line like theirs only used to the extent of one-third of its capacity simply because of the condition at the King William-street Station. The shareholders ought to proceed at once, under the Act they had obtained, with an important extension of their system. The directors proposed to go as far as Finsbury-pavement—opposite the Moorgate-street Station. They would start from the Borough Station as a branch, in order to get a station close to the London Bridge Station, the Brighton Company having promised to make a connection with its platforms by means of an underground passage. It would also be in connection with the terminus of the proposed Great Northern and City Railway, the prospectus of which had just come out, and which would, he hoped, obtain its money and construct its line, in which case they would have an exchange of traffic with it, so that their passengers would be able to go through on to the Northern system, and they would thus tap the enormous population that lay along the route of that line. It was believed that the sites could be obtained on terms which would be regarded as highly satisfactory by the shareholders, but of course the negotiations would take some time. What the directors asked was that the shareholders should give them authority to proceed for the acquisition of those sites for the ultimate purpose of carrying out the extension, but the Board did not propose to enter into any agreement involving any large expenditure without the specific authority of the shareholders.

Mr. Sampson Hanbury seconded the motion.

Sir Thomas Hanbury proposed the following amendment to the sixth paragraph of the report, relating to the extension of the line—namely, "That it is not prudent to proceed at present with the proposed extension of the line."

Mr. J. T. Middleton seconded the amendment.

After some discussion, a vote was taken, and ultimately the adoption of the report was carried unanimously.

After a dividend of 5 per cent. per annum had been declared on the preference shares and 1¼ per cent. per annum upon the consolidated ordinary stock, the retiring director (Mr. C. G. Mott) was re-elected, and Messrs. Turquand, Youngs, and Co. reappointed auditors.

A special general meeting was then held, at which the Bill to further extend the time for the purchase of lands for the railway and for raising the additional capital was approved.

COMPANIES' REPORTS.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY, LIMITED.

Directors: S. Wm. Silver, Esq. (chairman); Abraham Scott, Esq.; Matthew Gray, Esq (managing director); Robert Henderson, Esq.; the Hon. Henry Marsham; A. Weston Jarvis, Esq.

Report of the directors for the year ending December 31, 1894, to be presented at the thirty-first ordinary general meeting of the shareholders to be held at the Cannon-street Hotel, London, on Thursday, February 14, at 12 o'clock.

The annexed accounts show the net profit for the past year to be £41,961. 15s. 9d. Adding £28,952. 1s. 7d. brought forward, and deducting £25,000 interim dividend paid in July, there remains a disposable balance of £45,913. 17s 4d. The directors recommend the distribution of a dividend of 10s. a share, free of income tax, amounting to £25,000, making, with the interim dividend, a total payment for the year of 10 per cent., and leaving

Digitized by Google

£20,913. 17s. 4d. to be carried forward. The trading for the year has been comparatively unsatisfactory. Competition has reduced both the volume of general business and the rate of profit, and there have been but few orders for cables. The Silvertown and Persan factories are in good order. The Hon. H. Marsham and Mr. Jarvis, the directors retiring by rotation, offer themselves for re-election.

BALANCE-SHEET TO DEC. 31, 1894.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY.

Directors: Eustace J. A. Balfour, Esq. (chairman); Latimer Clark, Esq., F.R.S. (vice-chairman); Sir John H. Morris, K.C.S.I.; Gerald W. Balfour, Esq., M.P.; Bennett Fitch, Esq., M.I.C.E. General manager and secretary, Frederic J. Walker. Chief engineer, S. T. Dobson, A.M.I.C.E., M.I.E.E.

Report of the directors and abstract of accounts for the year ending December 31, 1894. The general meeting is to be held at the offices of the Company, Carnaby-street central station, Golden-square, W., on Tuesday, February 12, at 3 p.m.

The directors, in submitting their report for the year 1894, with accounts as certified by the Company's auditors, congratulate the shareholders on the improvement shown in the result of the year's trading. The business of the Company is steadily increasing, and the building extension in Carnaby-street, now almost completed, has been made none too early. It has also become necessary to add to the plant at Carnaby-street, and orders have been given accordingly. This involves an expenditure of capital beyond the amount already at the disposal of the directors, which they propose to meet by a further issue of a part of the £100,000 4 per cent. debenture stock created last year, and of which £30,000 has already been issued. The directors regret that the item of expenditure under the head of rates and taxes has so considerably increased. This is owing to a revaluation of the premises by the Vestry, which has been upheld by the Assessment Committee. An action has been instituted by the Attorney-General on behalf of the parish, alleging a nuisance from the plant at the Mason's-yard station. This station is now only used as auxiliary to the main station at Carnaby-street. No efforts have been or will be spared to prevent annoyance to the parishioners. The net earnings of the Company during the past year have amounted to £13,468. 4s. 10d. Of this sum, £5,498 was distributed in August last in payment of an interim dividend at the rate of 4 per cent. per annum for the half-year ending June 30, 1894, on the ordinary shares, and at 7 per cent. per annum on the preference shares. The balance, £7,970. 4s. 10d., together with the undivided profit of £120. 8s. 9d. from last year's account, leaves £8,090. 13s. 7d. now to be dealt with. The directors propose to divide this amount as follows:

	£	s.	d.
(a) By payment of a dividend at the rate of 7 per cent. per annum on the preference shares for the second half of the year	£3,500	0	0
(b) By payment of a dividend at the rate of 9 per per annum for the second half-year on the ordinary shares, making, with the interim dividend paid on August 1 last, a total distribution of 6½ per cent. for the year	4,495	10	0
(c) Amount to be carried forward to ordinary shareholders' undivided profit account	90	14	5
(d) Amount to be carried forward to founders' undivided profit account	4	9	2
	£8,090	13	7

Mr. H. Woodburn Kirby has recently resigned his seat on the Board, to the great regret of his colleagues. Sir John H. Morris, K.C.S.I., and Mr. Gerald W. Balfour, M.P., are the directors who retire by rotation under Clause 79 of the articles of association, and being eligible offer themselves for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths, and Co., also retire, and being eligible offer themselves for re-election.

HOUSE-TO-HOUSE ELECTRIC LIGHT SUPPLY COMPANY.

Directors: Henry Ramié Beeton (chairman), William Page (managing director), William Reginald Davies, Robert Arthur Germaine, William Francis Leese. Manager: Henry W. Bowden. Secretary: W. Coupland Weir.

Report of the directors and abstract of accounts for the year ending December 31, 1894.

In submitting to the shareholders the balance-sheet and accounts for the year ended December 31, 1894, the directors beg to report that the revenue account shows a credit balance of £6,263. 15s., which, with the balance of £43. 8s. 3d. brought forward from the previous year, makes a total of £6,307. 3s. 3d. After deducting £1,898. 11s. 10d. for interest paid on £30,000 debentures, and on temporary loans, the directors recommend that the balance be dealt with as follows:

In reduction of preliminary expenses	£500	0	0
In extinction of suspense renewal account	200	0	0
Depreciation account	1,450	0	0
Dividend of 7 per cent on £25,000 cumulative preference shares	1,750	0	0
In reduction of construction business development account	400	0	0
Balance carried forward to next account	108	11	5
	£4,408	11	5

The table given below shows the progress of the Company's electric lighting business during the last five years: The increase in the lights connected during the year 1894 was equivalent to 7,429 8-c.p. (35-watt) lamps, being the largest increase since 1890, and the directors consider that the shareholders are to be congratulated upon the fact that, notwithstanding an increase in revenue of £1,632. 0s. 10d. as compared with that received in 1893, the working expenses as compared with the same period show a decrease of £400. 10s. Since the issue of the last report additional mains have been laid in various parts of the area, and to meet the continual increase in the Company's business, arrangements are being made for laying down further plant and mains during the current year. As the amount of ordinary capital appropriated to construction business development account stands at £15,000, the directors propose to gradually write down the account to that amount, and to this end they have applied £400 out of the profits of this year. The directors regret to report that they have been advised by the secretary of the Leeds and London Electrical Engineering Company, Limited (to whom this business has been leased), that their accounts for the year ending March 31, 1894, will not admit of the distribution of any profit. The £30,000 6 per cent. first mortgage debenture bonds, which were redeemable on January 1, 1895, have been paid off, and £50,000 of 4½ per cent. mortgage debenture stock has been created, of which £40,000 has been issued. By this operation the Company is provided with an additional £10,000 without any increase in the annual amount required for interest. The directors, having had every reason to be satisfied with the manner in which Mr. Henry W. Bowden discharged the duties of chief engineer, have appointed him to the post of manager. Mr. H. R. Beeton and Mr. W. Page retire from the Board by rotation, and being eligible offer themselves for re-election. Messrs. Theobald Bros., Miall, and Co., the auditors of the Company, retire, and submit themselves for re-election.

The amount of electricity generated, sold, etc., for the past year (in Board of Trade units) is as follows: to private consumers by meter, 400,911; quantity used in works, 5,498; total quantity accounted for, 406,409; total maximum supply demanded, 430.

NEWCASTLE AND DISTRICT ELECTRIC LIGHTING COMPANY, LIMITED.

Directors: John D. Milburn, Esq., chairman; the Hon. C. A. Parsons, managing director; Sir B. C. Brown; Colonel W. M. Angus; Colonel H. S. Dyer; John B. Simpson, Esq. Jas. Patterson, secretary. W. D. Hunter, engineer.

Report of the directors to be presented to the shareholders at the eighth ordinary general meeting of the Company to be held at 57, Westgate-road, Newcastle-on-Tyne, on Monday, February 12, at 2 30 p.m.

The directors have pleasure in again reporting that the supply of current continues to give satisfaction to the Company's consumers. The installations connected to the Company's mains during the year are equal to 3,000 10-c.p. lamps, bringing the total up to about 21,500, and 431,239 units of electrical energy have been supplied, as against 388,422 units supplied in 1893. During the past year 2,327 yards of main and branch piping have been laid, together with 7,657 yards of main and branch cable. The condensing plant referred to in last year's report is now constantly at work, and the large saving effected in the cost of fuel and water has more than justified the amount spent upon its erection. The gross earnings during the year amount to £3,792. 11s. 8d., and after paying interest and making provision for depreciation, and writing off £200 from formation expenses, your directors are able to recommend a dividend at the rate of 3½ per cent. for the half-year ending December 31 (less income tax), which, together with the interim dividend paid in July last, makes the dividend 6 per cent. for the year. Colonel W. M. Angus and Mr. John B. Simpson retire by rotation, but are eligible, and offer themselves, for re-election as directors. The auditors, Messrs. Strachan and Co., also offer themselves for re-election.

CITY OF BATH ELECTRIC LIGHTING AND ENGINEERING COMPANY, LIMITED.

Directors: T. O. Callender, London, chairman; Alfred Pitman, Bath; B. H. Van Tromp, London; C. J. Wharton, London; J. B. Wood, London; Ernest Pitman, Bath. Secretary: Wm. Jeffery, 2, Northumberland-buildings, Bath. Engineer and manager: G. F. Metzger, A.I.E.E.

Report of the directors to be presented at the fourth annual general meeting of the Company, to be held at the works of the Company, Dorchester-street, Bath, on Wednesday, February 13, 1895, at 2.30 p.m.

In submitting the accounts for the year 1894, your directors think there is every reason for satisfaction in the improved position

Digitized by Google

of the Company's affairs. The profit on the year's working, after charging all repairs to plant, mains, and machinery to revenue, is £702. 8s. 7d., which compares very favourably with the loss of £306. 15s. 11d. made in 1892, and the profit of £188. 1s. 4d. made in 1893. Your directors have thought it right to clear from the books all long outstanding debts, and believe that ample provision has been made for every possible contingency. The items bad debts £49. 16s. 4d. and the balance £89. 11s. 6d. at the debit of profit and loss from the past year, have reduced the available balance to £563. 0s. 9d., which would have sufficed to pay a small dividend. After consideration, however, it has been deemed best in the interests of the Company to carry this balance forward. Considerable sums have been spent on maintaining everything in first-class working order, and this expenditure has been charged against the current year's revenue. It will be noticed that a large amount has been expended during the year on capital account. A new engine has been purchased for the public lighting plant, and the dynamos for that service have been entirely rearranged. New switchboards for the private incandescent services have been erected, and some of the furnaces have been fitted to burn oil fuel. Additional transformers and meters, etc., have been purchased and service lines laid down. The directors have every reason to be satisfied with the expenditure, the good results of which will be more clearly shown in next year's balance-sheet. It is anticipated that by Christmas the existing station plant will be fully loaded, and in this event there is no doubt that the accounts will show most excellent results, and that the Company will be in a very satisfactory financial position. The confidence of the citizens of Bath in the Company is shown in the most satisfactory increase in the number of lamps connected with the mains. During the last three months these have equalled 653 8-c.p. lamps, so that at the end of the year there were 8,327 lamps wired, a very large proportion of which are in use at one time. The plant is sufficient for the supply of current to 10,000 lamps, allowing one spare set of machinery complete; the Company therefore can safely add 1,673 lamps without any further expenditure. The shareholders have every reason to be satisfied with the working of the Company during the late disastrous floods. For four days the public were depending on this Company solely for the supply of artificial light, and your directors believe that the signal success attending their operations during that period will not be forgotten by the inhabitants. The Board desire to put on record their appreciation of the energy of their manager, and of the cordial assistance given him by his staff during this trying time. The plant, machinery, and mains are in excellent condition, and at no period of the Company's history have they ever been in so thoroughly efficient and satisfactory a state. Your directors are of the opinion that the efficiency of the station and its economical working can be still further secured by a moderate additional expenditure of capital. This expenditure will probably be made early this summer, and there will be no difficulty in raising whatever money is necessary for it. In accordance with the policy settled at the special meeting of the shareholders held on September 13, 1894, application was duly made to the Board of Trade for a provisional order in substitution of the license now held, and the consent of the local authority was applied for, but withheld. A meeting of the Town Council was summoned at the last moment and held on January 14, at which it was resolved to oppose our application, and a resolution was passed that the Corporation themselves apply for a provisional order for the district in question. The interests of the Company will be well looked after by E. B. Titley, Esq., with whom will be associated, as parliamentary agent, Sydney Morse, Esq., the most experienced adviser in questions relating to the Electric Lighting Acts. The directors have full confidence in the fairness and justice of the Board of Trade, and as the matter is now in their hands it is unnecessary to discuss it. The directors having waived all remuneration during the past two years, propose to appropriate out of the profits the sum of £175 as directors' fees for the year 1894. Mr. T. O. Callender and Mr. C. J. Wharton are the directors who retire by rotation, and, being eligible, they offer themselves for re-election.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Madrid.—The General Directors of Posts and Telegraphs invite tenders by 19th inst. for 1,000,000 rolls of telegraph paper.

Maidstone.—The Urban District Council are open to receive offers for the transfer of their electric light order. Application should be made to the town clerk.

Hampstead, N.W.—The Vestry of St. John, Hampstead, invite tenders by the 14th inst for the supply of lubricating oil, tools, implements, and other electrical engineers' stores, carbons, and lamps. Further particulars may be obtained of the surveyor, at the Vestry Hall, Hampstead.

Weybridge.—The Urban District Council invite tenders for the public lighting of Weybridge on and after September 29. Tenders should state the number of public lights proposed, the illuminating power, and price per light. Tenders should be sent to Mr. Geo. Wheeler, clerk pro tem. to the Council, before 20th inst.

Islington.—Tenders are invited for the supply of alternate-current meters and converters by the Vestry of St. Mary, Islington. Specifications and full particulars may be obtained on application to the electrical engineer, 50, Eden-grove, Holloway, N., on or after 13th inst. Applicants will be required to deposit the sum of £1. 1s., which will be returned on receipt of a *bond fide* tender.

West Ham.—The Town Council invite tenders for a technical institute and public library in Romford-road, and invite designs for the same. Premiums of £250 £150, and £100 respectively will be paid to the authors of the designs which are placed by the assessor first, second, and third in point of merit. Particulars can be obtained on application to Mr. Fred. E. Hilleary, town clerk, Town Hall, West Ham. on payment of a deposit of £1. 1s., which is returnable. Designs by May 1.

RESULTS OF TENDERS.

Bristol.—The tender of Messrs. F. W. Ball and Co., Unity-street, has been accepted by the Corporation for the installation of the electric light at the Guildhall and a portion of the Council House. The amount was £438. There were 17 tenders.

Nelson.—The tender of Messrs. Spagnoletti and Crookes, St. James's Hall, Burnley, has been accepted for lighting Stanley-street Chapel, Nelson, with electricity There also tendered: D. and G. Graham, Glasgow; Berry and Pope, Burnley; Fletcher, Hirst, and Co., Burnley; S. J. Waring and Sons, Manchester; E. Scott and Mountain, Newcastle; J. H. Ward and Co., Manchester; Maunsell, Mercier, and Co, Manchester; Briscoe and Shaw, Blackburn; Manchester Edison-Swan Company, Manchester; Nelson Electrical Engineering Company, Nelson; Calvert and Co., Manchester; Bennett and Druce, Preston; J. Hargreaves, Nelson; Coates Bros., Nelson.

London, N.W.—The Metropolitan Asylums Board have accepted the tender of Messrs. Vaughan and Brown, of Kirby-street, E.C., to provide and lay mains, wires, etc., in connection with the lighting of the North-Western Hospital by electricity, in accordance with the plans and specification prepared by Prof. Ayrton, the consulting engineer. The following is a list of the tenders received:

H. Thorpe and Waring, Theobald's-road, W.C.	£1,180	10	0
Vaughan and Brown, Kirby-street, E.C.	1,239	0	0
J. Sax and Co., Limited, Ridgmont-street, W.C.	1,335	0	0
Paterson and Cooper, Dalston, N.E.	1,355	0	0
Graham and Biddle, Oxford street, W.	1 392	10	0
Roger Dawson, Limited, Berners-street, W.	1,450	0	0
Fowler, Lancaster, and Co., Limited, Birmingham.....	1,467	19	6
Gilbert and Co., Kensington, W	1,567	0	0
Strode and Co., Regent's Park, N.W.	1,827	0	0
Brush Electrical Engineering Company, Queen Victoria-street, E.C.	1,900	0	0
T. Potter and Sons, Limited, Oxford-street, W.	2,198	0	0
Crompton and Co., Limited, Lillie-road, S.W.....	2,575	0	0
F. A. Glover and Co., Queen Victoria-street, E.C.	2,667	18	0

The committee state that the amounts above quoted are not the exact sums for which each firm offer to do the work. Each tender is made up of the above-mentioned figures and a short schedule

Digitized by Google

of prices. The tenders were so obtained on the advice of the consulting engineer, but it is not anticipated that the cost of the work will much exceed the amounts above quoted. Prof. Ayrton's estimate for the whole work was £2,116, but this figure includes about £900 for the laying of some of the mains which the Vestry of Hampstead have now undertaken to do, and for wiring buildings not yet erected. The cost of the whole work under the tender now recommended will not exceed the estimate as above qualified.

Newport.—Tenders have been received by the Museum Committee from the following for wiring and fitting the new museum buildings:

Allam and Co., Cardiff	£46	10	0
W. A. Baker and Co., Newport	74	0	0
Arnold and Co., Newport	80	0	0
Alger and Son, Newport	83	10	0
Davis and Son, Derby	88	0	0
Newport Electric Lighting Company	93	0	0
Hatcher and Co., Cardiff	95	0	0
Fergus and Co., Cardiff	141	5	0

The first-mentioned tender has been accepted by the committee, the stipulation being made that the firm shall guarantee to carry out the work to the Town Council's satisfaction, and to comply with the fire insurance company's requirements.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,279.

Great Northern Telegraph Company.—For the month of January the receipts were £23,200.

Dundalk.—The Town Commissioners have instructed the surveyor to prepare a report on electric lighting with the use of water power.

Maidstone.—The report of the Electric Lighting Committee will be brought forward at the next meeting of the Urban District Council.

Cuba Submarine Telegraph Company.—For the month of January the receipts were £67 more than for the corresponding period of 1894.

Eastern Telegraph Company.—The receipts for the month of January were £70,674, as against £64,851 for the corresponding period of 1894.

Direct Spanish Telegraph Company.—For the month of January the receipts were £1,878, as against £1,909 for the same period of 1894.

Blackrock.—The Town Commissioners of Blackrock (Ireland) have decided to let the question of electric lighting remain in abeyance for the present.

Telegraph Construction and Maintenance Company.—The Board recommends a balance dividend of 15 per cent., making 20 per cent. for the year 1894.

Eastern Extension Telegraph Company.—For the month of January the receipts show an increase of £1,638 as compared with the corresponding period of 1894.

Fermoy.—The Town Commissioners will shortly consider the report prepared by Mr. T. Tomlinson, who suggests the use of water power in conjunction with gas-engines.

Office-Lighting.—The North-Eastern Railway Company have entrusted to Messrs. Drake and Gorham the work of lighting their new offices in Great George-street by electricity.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 3rd inst. amounted to £924, as compared with £632 in the corresponding week of last year.

Medical Electrical Institute.—Mr. Justice North has made an order for an interim appointment of a receiver or manager in the case of Ross *v.* the Medical Electrical Institute, Limited.

Priestman Bros. Limited.—A supervision order has been made in the case of this Company. Mr. Eve, Mr. Sheldon, Mr. C. Macnaghten, Mr. Nepean, and Mr. Pike Glasgow were the counsel engaged.

Stage-Lighting.—A meeting of the shareholders of the Pavilion Music Hall was held on Monday, at which the Chairman stated that there had been additional outlay occasioned by the installation of the electric light on the stage.

Business Change.—Messrs. King, Mendham, and Co., of Narrow Wine-street and Fairfax-street, Bristol, inform us that they have closed their London agency, and that all communications should now be sent direct to Bristol.

Portsmouth.—The Town Hall Committee have recommended the Council to accept an offer of £200 for the machinery formerly used for electric lighting purposes at the Town Hall. The plant was purchased about six years ago at a cost of £1,970.

Personal.—Mr. A. S. Blackman is at present in charge of the Aberdeen Corporation electric light station. He intends applying for the post rendered vacant by the resignation of Mr. E. T. Ruthven Murray, who is going to the Worcester station.

St Luke's.—The Vestry have unanimously decided to support the Vestry of St. George-the-Martyr, Southwark, in their appeal to the Board of Trade against allowing the construction of electrical transformer-chambers in the main thoroughfares of the Metropolis.

Penarth.—A fire, which resulted in the total destruction of the electric lighting plant at the Penarth Dock, occurred on Wednesday. The plant belonged to Messrs. J. B. Saunders and Co., Bute Docks, Cardiff.

Water Power.—"Power," care of Messrs. Deacon and Co, of 154, Leadenhall-street, E.C., advertises that he has available water power for electrolytic and other manufacturing processes, to the extent of many thousand horse-power, at 16s. per horse-power per annum.

Change of Address.—Messrs. Howard B. Little and Co., of 20, Eldon-road, Kensington, W., inform us that all communications and enquiries should now be directed to 36, Shaftesbury-avenue, W. The company are now making a feature of the winding of induction coils and transformers, so as to meet special requirements.

City and South London Railway.—The receipts of the Company for the week ended February 3 were £1,021, against £951 for the corresponding week of 1894, or an increase of £70. The total receipts for the current period of the present half-year are £5,020, against £4,790 in the corresponding period of 1894, an increase of £230.

Sunderland.—The Town Hall Committee have held a meeting at which the principal business was the consideration of the estimates for the year ending March 1896. The estimated expenditure was put down at £1,470. 7s. 10d., the principal item being £450, the cost of the installation of the electric light and alterations to gas fittings.

Belfast.—A meeting has been held of the Town Council at which Alderman Pirrie moved the adoption of the report of the Electric Light Committee, which set forth that the central station had been sufficiently completed to enable them to supply current, and the installation had been inaugurated on the 23rd ult. The report was accepted.

Dublin.—The Dublin United Tramways Company have received the sanction of the Privy Council for the extension of their system to Dolphin's Barn, the doubling of the North Circular road line, the laying down of an interlacing double line in South Great George's-street, and the formation of a junction at Merrion-square for traffic with Rathmines.

Transfer of Business.—Messrs. E. P. Allam and Co., of 49, Finsbury-pavement, London, E.C., inform us that they have purchased the electrical engineering business lately carried on by Mr. D. F. Adamson at 72, Finsbury-pavement, E C, and that it will be continued at the former address. The company also have offices at 16, Albert-chambers, Cardiff.

New-Mayne Electric Rudder Motor Syndicate, Limited.—This Company has been registered, with a capital of £20,000, to acquire and turn to account the English patent and one moiety of the foreign patents to be taken out, if considered advisable, of Messrs. New and Mayne's invention for an electric rudder motor, which is covered in Great Britain by letters patent.

Partnership.—Mr. A. T. Salisbury-Jones, of 33, Old Broad-street, informs us that, in consequence of the increase in his business during the last few years, he has now taken into partnership Mr. Guy L. Bidwell, who has been connected with him in various transactions for some years past. The business will be continued under the style of Messrs. Salisbury-Jones and Bidwell.

Peterborough.—The Town Council have appointed the Mayor, Alderman Barrett, and Councillors Clifton, Nichols, and Simpson, a deputation to wait upon Mr. G. C. W. Fitzwilliam with regard to the use of a piece of land on the west side of the cattle market, as a central station for the supply of the electric light in the city, or to ascertain if an alternative site could be obtained.

Catalogue.—There has been issued by Messrs. Hayward Tyler and Co., of 90 and 92, Whitecross-street, London, E.C., a catalogue of electrical plant, which contains some details concerning the methods of electric lighting, and also illustrates direct and alternating current dynamos, high-speed vertical engines, mine pumps, portable electric lighting plants, accumulators, measuring instruments, fittings, lamps, boilers, gas-engines, etc.

Trade Note.—Messrs. W. T. Glover and Co., electric wire and cable makers, of Salford and London, have arranged for Mr. Walter Blenkarn to represent them in the western, southern, and eastern counties of England. Mr. Hartford, who has hitherto represented them, still continues with the firm, and will take the northern counties. This addition to the staff has been rendered necessary by the rapid increase in the company's business.

Eton.—A meeting of the Eton Urban District Council has been held at the Board-room, Barnes Pool Bridge, to consider and decide as to giving consent to the provisional order which it is proposed by the Windsor Corporation to obtain for the purpose of supplying electric light in the district, Eton being a portion of the proposed area of supply. The chairman, Mr. E. C. Austen-Leigh, presided. After a lengthy discussion it was agreed that the consent be given.

Hargreaves and Shaw, Limited.—This Company has been registered, with a capital of £5,000, to acquire and take over as a going concern the business of electricians and mechanical engineers now carried on by Ellis Hargreaves and Ellis J. Hargreaves, as Hargreaves and Co., at Atlas Works, Curzon-road, Ashton-under-Lyne, and to enter into an agreement with the vendors for the purpose and to carry on the business of an electric light company.

Ibo Syndicate, Limited.—This Company has been registered, with a capital of £50,000, to construct, execute, carry out, equip, improve, work, develop, administer, manage, or control, in Africa or elsewhere, public works and conveniences of all kinds, rail and tramways, docks, harbours, piers, wharves, canals, reservoirs, embankments, irrigations, water, gas, electric light, telephonic,

Digitized by Google

telegraphic, and power supply works, and hotels, warehouses, markets, etc.

Stafford.—With regard to the charge for electricity, Alderman Peach at Tuesday's meeting of the Town Council said that the committee had decided to recommend the Brighton system, in which the charge was 8d. per Board of Trade unit for the maximum hours in which the electricity was used, and 4d. per unit after this maximum had been passed. This, he contended, would put the small consumers on the same footing as the large ones The report was adopted.

Tunbridge Wells.—A meeting of the Town Council was held on Wednesday, when, in reply to questions by Councillor Jenkinson as to the cause of alleged electric light explosions in London and elsewhere, the Mayor said he could reassure them as regarded Tunbridge Wells, as there was no likelihood of such explosions in the streets. The mains were not laid down in Tunbridge Wells as they were in London. Even as regarded London explosions, it had been shown that they were due to gas.

Oldham.—A meeting of the Town Council was held on Wednesday, when Alderman Emmott asked that a balance-sheet should be issued with regard to the working of the electric light. Alderman Smith (chairman of the Electric Lighting Committee) said that a balance-sheet would have been issued before now, but certain of the machines were unsatisfactory, and until such time as the engineer would pass them nothing could be done in the way of placing a balance-sheet before the Council.

Llanelly.—The Llanelly Town Council held a meeting on Monday, at which the question of electric light came up on a recommendation from the Estate Committee that tenders be invited for lighting the Town Hall, Athenæum, Market Hall, and other public buildings, as well as a portion of the town, by electricity. After a discussion, eight members voted for and eight against the adoption of the recommendation. The chairman gave his vote in favour, and the minute was adopted.

Hastings.—A meeting of the Town Council was held on Friday last, at which, on the consideration of a bill of £323 for lighting the front line by electricity, Councillor Hutchings suggested that the electric light company should be asked to reduce the charge, on the ground, as he alleged, that the lighting was a failure. He moved that the matter be referred back to the committee. Alderman Bradnam seconded, observing that the lighting was not altogether satisfactory, and the motion was adopted.

St. James's and Pall Mall Company.—The transfer books of the ordinary and preference shares of this Company will be closed until the 18th inst., preparatory to the payment of dividends for the half-year ended December 31 on the ordinary and preference shares. Mr. F. J. Walker, the general manager and secretary, informs us that the number of units sold to customers during 1894 was 1,569,884, and that 60,037 8-c.p. lamps were connected to the mains at the end of 1893, as compared with 75,217 8-c.p. lamps at the close of 1894.

Copper.—Supplies of copper came forward faster in the second half of January than in the first, and deliveries did not keep pace with the arrivals. The American shipments again show a decided disposition to grow, nearly 1,000 tons more coming to Europe in January than in December. But for this increase stocks would have shown a diminution; as it is, they are 184 tons larger than on December 31, and 781 tons greater than on January 15, and prices are consequently weaker. The visible supply is now larger than at any date since March, 1893.

Eastbourne.—On Monday, at a meeting of the Town Council, Councillor Duke referred to the explosion in Terminus-road, and was about to explain the circumstances under which it occurred, with a view to showing that the electric lighting company did not contribute to the accident, when he was interrupted by Councillor MacQueen, who pointed out that this matter had been referred to the Board of Trade, and that possibly an enquiry might be held by them. He asked, therefore, if it was not out of place then to go into the matter. After some slight discussion the matter dropped.

Aberdeen.—A statement was submitted to the Town Council on Monday, showing the income and expenditure in connection with the electric lighting undertaking for the 10 months ending December. The capital account brought out a balance at debit of £619, and the net revenue account a debit balance of £217. It was decided that the price of current for the present quarter should be fixed at 6d. per Board of Trade unit. It was reported that the offer of Messrs. New and Mayne to instal a system of electric lighting in the municipal buildings for £203. 18s. had been accepted.

Derby.—The report of the Electric Lighting Committee of the Town Council stated that 100 meters had been ordered. A contract for coal had been let to Messrs. F. and H. R Johnson. Messrs. Siemens and Co. had made a constructional alteration in the arc lamps. Five transformers had been ordered. The committee hoped to submit a full report as to the settlement of the contractors' account at the March meeting of the Council. The accounts had been delayed owing to the illness of one of Messrs. Siemens's staff. The report was adopted on the proposition of Alderman Marsden.

Aberdeen.—A meeting of the Gas Committee of Aberdeen Town Council has been held, when Mr. Cran, city chamberlain, submitted a report in reference to the electric lighting department, which showed that up to date £1,850 4s. had been paid for current, and that, after allowing for interest and depreciation, a reduction had been made in connection with the deficit at the date of the last balance. In view of this fact, the committee were of opinion that it would be advisable to recommend a reduction in the price of the current for the present quarter of 1d. per unit, making the price 6d. per unit.

Mansion-Lighting.—A complete electric light installation has been fitted up in Elveden Hall, Norfolk, which was recently purchased by Lord Iveagh. The installation comprises some 500 incandescent lamps, two sets of steam-engines and dynamos, and a double battery of accumulators. Electric power is transmitted some distance for working a pump for supplying the house with water. Messrs Edmundsons, Limited, were the contractors, and the work was carried out to the specification and under the superintendence of Mr. A. A. C. Swinton as consulting engineer.

Proposed Welsh Electric Tramway.—Several engineers on Saturday inspected the ground from Colwyn Bay to Conway, and from Conway through Deganway to Llandudno. It is proposed to lay an electric tramway along the above-mentioned route. If the Llandudno District Council will grant their permission for the tramway to go along Mostyn-street and Mostyn-street extension to Craigside (the eastern end of the town), the work of laying down the Deganway portion will be at once commenced, and the survey of the whole line will be gone on with and a provisional order will be applied for in the present session of Parliament.

Worcester.—A meeting of the Town Council was held on Tuesday, when Mr. Williamson said the total loss on the electric lighting works for the first quarter was less than £100, and he held out strong hopes that by next winter the scheme would be bringing in a profit. He further stated that the builder's extras in the erection of the generation station amounted to between £4,000 and £5,000. The committee regarded that as very unsatisfactory, and they proposed to enquire into the matter exhaustively and see what extra work had been done and by whose authority. The Council asked the committee to report fully upon the matter.

National Telephone Company, Limited.—The report of the Company for the half-year ended December 31 states that the income accrued in respect of the business of the half-year amounts to £378,789, an increase of £40,861; and the expenses amounted to £205,192, an increase of £41,339. The net result (after deducting the Post Office royalties, amounting to £34,953) is a profit balance of £138,642, as compared with £142,589. The directors recommend a dividend at the rate of 6 per cent. per annum on the first and second preference shares, and 5 per cent. per annum on the third preference and ordinary shares; they also propose to transfer £35,000 to the reserve fund, and to carry forward £3,379.

Kendal.—A meeting of the Town Council has been held at which Councillor Littlewood said the circular that had been sent out, enquiring if burgesses would become customers for the electric light, was not remarkable for its perspicuity. It did not afford any reliable information to go upon. To say that the cost would be 7d. or 8d. per Board of Trade unit, which was equal to gas at about 5s. per 1,000 cubic feet, was very vague. After wandering on in this style for some time, a desultory and foolish conversation ensued, which led to nothing. The Rural District Council of South Westmoreland have heard a statement from a representative of the electric light company, but have deferred consideration of the matter.

Bolton.—The Gas and Electricity Committee of the Corporation have abolished the differential scale of charges for the supply of electricity, and have introduced a uniform rate of 6d. per Board of Trade unit. Mr. John H. Rider, the borough electrical engineer, states that at this rate the net price, with a discount of 10 per cent., will work out at 5·4d. per unit. It is proposed to borrow £18,000 for an extension of the electric lighting. The Finance Committee of the Town Council have considered the question of lighting the offices in the Town Hall by electricity. It was resolved to recommend that estimates be obtained for lighting the Albert Hall and the offices in the Town Hall, with the exception of the waterworks offices, by electricity.

Appointments.—The Hyde Technical Instruction Committee require the services of a competent person to act as organising and general secretary, at a salary of £200 per annum, who will be required to enter upon his duties in May next, and to devote his whole time to the work of the committee and its sub committees. Applications, stating age and qualifications, together with copies of three recent testimonials, and enclosed in an envelope endorsed "Secretary," to be forwarded to the town clerk, Hyde, so that the same may be received by him on or before March 9. A full statement of the duties and form of application will be supplied by Mr Geo Stevens, town clerk.—The Gas and Electricity Committee of Salford require two switchboard attendants. Particulars are given in our advertisement columns.

Queenstown.—A meeting of the Town Commissioners has been held, at which Mr. Long proposed a resolution, "That a competent electrical engineer be employed, at a sum to be agreed upon, to report to the Board the practicability of lighting Queenstown by electricity by the present machinery at the pumping station, and the probable cost of same." He said they had offers from electrical firms that they were prepared to give the Commissioners every advice on the matter, and when they had got all the information on the subject they could adopt it or not. He would suggest that when the business was over, their monthly meeting should stand adjourned until Mr. Hammond, electrical engineer, who had offered to give them information on the subject, would be present. Mr. Campbell seconded the motion, which was agreed to.

Wigan.—A meeting of the Gas Committee of the Town Council has been held, at which the report of the Electric Lighting Sub-Committee on schemes and tenders submitted by various firms was read, and it was resolved that the report be printed and circulated

Digitized by Google

to the members of the Council, and that the tender of Messrs. John Fowler and Co. be accepted subject to the sanction of the Local Government Board being obtained for the borrowing of the money necessary for the purpose on the understanding that the work is not to be commenced and no liability incurred until such sanction is obtained. The Council was recommended to apply to the Local Government Board for power to borrow £20,000 for carrying out the scheme, and the gas engineer was instructed to prepare the necessary plans. The chairman, vice chairman, and Messrs. Richards, Johnson, Rigby, and Smith were appointed a sub-committee to supervise the work.

Newhaven.—The Board of Trade have forwarded to the Urban District Council a copy of Section 4 of the Electric Lighting Act, 1888, and requested the Council to inform the Department whether there were any electric lines or works such as were contemplated by the section within the district The Chairman stated that the information sought for in the communication could be readily supplied by Mr. Knightley, who would report that there were certain lines laid down for the supply of electric light. Of course he referred to the company's system. The object of the Board of Trade was that where such lines existed they should be so laid as not to interfere with the public service of telegraphs either directly or indirectly. The local authority was made responsible for informing the central department of any such lines being laid, so that the Board of Trade might take the necessary steps to protect the telegraph lines and other things connected with the postal service.

The Proposed Acton Electric Tramway.—In our last issue we recorded the adverse decision of the London County Council in this matter. It has also been before the Middlesex County Council. Their Parliamentary Committee reported in reference to the London United Tramways provisional order that it proposed to authorise the promoters, with the consent of the Board of Trade, to work the tramways by means of electrical or other mechanical power. As they were advised that this would enable the promoters to use steam power, to which the Council had strongly objected in the case of the North London tramways, and as the Council had not been asked to consent to the order, the Parliamentary Committee had directed the county solicitor to take the necessary steps for the lodging with the Board of Trade of a petition against the scheme. The committee recommended the Council to approve their action in the matter, and to empower them to take such steps as they might consider necessary to protect the interests of the county. The Council adopted the recommendation.

Eccles —On Monday, Mr. Alderman Kendall, at a meeting of the Town Council, moved the adoption of the report of the Town Hall, Tramways, and Electric Lighting Committee, which stated that "having carefully considered the question of the advisability or otherwise of carrying out the powers conferred by the Eccles Electric Lighting Order, 1893, upon the Council, and the information and advice which they have received on the subject, the committee are of opinion that the time has arrived when the Council may safely proceed with a scheme for electric lighting in the borough." Mr. Kendall remarked that at present it cost between £1,200 and £1,400 a year to light the streets of the borough with gas, which meant a rate of about 3½d. in the pound. An eminent authority who had been consulted said that the streets could be lit for about £780, or that at any rate a saving of something like £300 a year in the cost of street-lighting would follow the adoption of electricity. Many other towns were adopting the electric light, and he thought Eccles should follow their example. The adoption of the minutes was carried after some discussion.

Cardiff.—A meeting of the Lighting and Electrical Committee of the Cardiff Corporation was held on Tuesday afternoon. The committee first visited the electric light station, and afterwards assembled in the borough engineer's office. The Mayor said that Messrs. Siemens and Co. had signified their intention of handing over the work complete to the Corporation in about three weeks' or a month's time, and in consequence of this they had to consider the question of discontinuing the lighting of the town by gas. Alderman Jacobs asked what had been the cause of the great delay, and Mr. Massey, the electrical engineer, explained that it was in consequence of Messrs. Siemens wanting to give more perfect lighting at the same cost and to give complete satisfaction to themselves. Some discussion ensued, in which the Mayor stated that it was the intention of the Corporation to run the engines both day and night. Mr. Harpur asked to be relieved of the responsibility of looking after the station at Canton. It was resolved that a sub-committee be instructed to approach Mr. Franklyn (in Messrs Siemens's employ at Cardiff) with the object of securing his services at a salary of £200 a year.

Cheltenham.—The borough surveyor having reported progress to the Electric Lighting Committee of the Town Council, he mentioned at a meeting of the Town Council last week that for executing current repairs a 6in. lathe should be obtained, the cost of which would be £35. With regard to the claims for compensation arising out of street accidents caused by the electric lighting works, it was resolved to settle with Mr. Muller, and to allow the town clerk and borough surveyor to see Mr. Millns on the accident alleged to have befallen him. Mr. R. E. Steel, solicitor, wrote claiming £20 compensation on behalf of Mrs. M. A. Wickham, of Southampton Villa, High-street, for injuries sustained by her having fallen over some planks on the footpath at the High-street corner of the Bath-road. It was resolved that the town clerk should enquire into the matter and report to the next meeting. A representation of the Public Library Committee that this committee should supply the electric light to the library free of cost was considered; but it was resolved that the committee could not recommend a free supply, but would light the library for £50 per annum (the charge for gas last year having been £57. 18s.), the public library to undertake to do their own wiring.

Trowbridge.—The Urban District Council have held a meeting at which the clerk read a letter from Mr. Medhurst, offering himself as an expert to the Council before they made application to the Board of Trade for a provisional order for electric lighting, because it was, he said, most essential that an order, to be of value commercially, should contain the best and most suitable definition of compulsory and permissible areas. He suggested that he should be allowed to instruct one of his assistants to make a thorough house-to-house canvass in the most important streets of their town, and that afterwards he should report to the Council on the whole electric lighting question, such report to contain recommendations as to compulsory and permissible areas and site for generating station. His fee for preparing an exhaustive report and plans for the house-to-house inspection referred to would be 40 guineas, exclusive of out-of-pocket expenses. The Chairman said the General Purposes Committee had the letter read to them, but they did not make any remark upon it. Since then their surveyor had received another letter. This was from Messrs. Casper and Lion, of London, who said they intended to tender for the lighting supply of the town. and asked the surveyor to furnish them with certain particulars. Both matters were allowed to drop.

Leeds Tramways.—As mentioned in our last issue, a further meeting of the Leeds Tramways Committee was held on Monday, when the haulage question again came up for consideration. The city engineer, Mr. Hewson, in accordance with instructions, presented a report on the cost of constructing and working an electric conduit system in the centre of the town. The committee resolved to recommend the adoption of this report. The proposal is that this system should be in use from Boar-lane, along Briggate and New Briggate, to the dispensary; from Boar-lane, in another direction, to the junction of Hunslet-lane with Hunslet New-road; from Briggate, along Wellington-street as far as Queen-street; and from Boar-lane, on the Headingley section, as far as the Bank of England, in Park-row. For the other parts of the city the committee recommend the Council to adopt the overhead system. The members are of opinion that the pillars and wires that would be required for the working of the overhead system in Briggate, Boar-lane, and the other central thoroughfares mentioned, would be an inconvenience, and they believe that the two systems—the conduit for the centre of the city, and the overhead for outside—can well be worked together. The actual capital cost per mile of the overhead electric system is said to be about £10,500, and of the conduit system about £14,500 The report of the Tramways Committee to the full Highways Committee has not yet been drafted, but at Monday's meeting four members were constituted into a special sub-committee for this purpose.

Birmingham —The Town Council met on Tuesday, when Mr. Martineau, in connection with the matter of the new technical school, moved that the committee be authorised to purchase additional apparatus and appliances at a further cost of £4,000; to expend £14,000 in providing the fittings for the new technical school, and removing machinery, etc., from the present temporary premises; £6,080 in providing electric lighting and fittings and motive power; and £3,340 in architect's and electrical engineer's commissions, etc.; and that the Finance Committee be instructed to borrow £27,420 for such purposes. Mr. Parkes seconded the motion. Mr. Bradley moved as an amendment that with regard to the proposed electric light installation, the committee be instructed to accept the lowest tender on the specification originally issued. He complained, that after first asking for a limited number of tenders, the committee had applied publicly for tenders, and if the resolution were passed the Council would be doing an injustice to the firms the committee invited to tender in the first instance. Mr. Bishop seconded the amendment. Alderman Pollack proposed as another amendment that that part of the report which related to the fitting and lighting of the new school, should be referred back for the purpose of enabling the committee to supply further and fuller particulars of expenditure under the various heads. Alderman Clayton said he was going to move that the consideration of the report be adjourned, and that the committee be instructed to report fuller details of the various tenders for the supply of apparatus, fittings, and electric power, and also their objection to lighting the building by gas after communication with the gas department. Ultimately Mr. Clayton's amendment was accepted.

New Swindon Junior Engineering Society.—The annual conversazione of the Swindon Junior Engineering Society took place last week, when the medals were presented by Mr. W. Dean, the president of the society. A large company was present, including Canon the Hon. M. Ponsonby, Messrs. G. J. Churchward, D. E. Marsh, W. H. Williams, E. C. Riley, and W. H. Stanier, Mr. Hooper Deacon, Mr. Douglas T. Heap, etc. Mr. Dean, in a brief address, said the society had been in existence for a couple of years. During the 1893 session five papers were read by three members, but during the next session 10 papers were read by 10 members. Messrs. Churchward, Marsh, and Williams had been asked to adjudicate upon the various papers, and they reported that the task of selecting the winners of the prizes was very difficult, as the papers were of uniform excellence. In the 1893 session Mr. A. E. Leader secured the medal, Mr. T. C. Davison receiving honourable mention; whilst in the following session Mr. H. G. Cotsworth's paper secured him the award, Mr. W. R. Bird and Mr. G. H. Burrows being especially mentioned. The collection of scientific instruments and other objects of interest were keenly examined,

Digitized by Google

Messrs. Crompton and Co., of London, made a large display of electrical exhibits—their several uses being explained by Mr. D. T. Heap. The samples, together with the bare copper systems used in underground mains, attracted considerable attention, whilst the electrical cooking and heating apparatus proved of interest. Current indicators, voltmeters, and other instruments were displayed. Sir F. Abel's apparatus for determining the temperature at which the vapour of light mineral oils for burning, etc., becomes inflammable, Boverton Redwood's viscometer, and other articles were sent by Mr. H. W. Harris; whilst Mr. A. Nash displayed an astatic galvanometer, telephone transmitter, galvanometer, microphone, electromagnet, and kaleidoscopes, which he had constructed. An arrangement of telephones and recording apparatus, the work of Mr. E. J. Tincknell, was also shown.

Liverpool.—A meeting of the Special Lighting Committee of the Liverpool Corporation has been held, at which there was read a letter from Mr. M. F. Radcliffe, solicitor to the Liverpool Electric Supply Company; also reports of the city engineer and the deputy town clerk. It was moved by Mr. Taylor, seconded by Mr. Petrie, that the Council be recommended to consent to the application by the Liverpool Electric Supply Company, Limited, for a provisional order to carry out the arrangement made with the company at the enquiry on the proposed extension of the city boundaries, provided such order is withdrawn if the order for the extension of the city boundaries is not confirmed by Parliament in the ensuing session, and that the Council be recommended to object to the application for any other purpose. On a division there appeared for the motion three—viz., Mr. Taylor, Mr. Petrie, and Mr. Williamson—against it one—viz, the chairman. The motion was therefore carried. At Wednesday's meeting of the Town Council, Mr. Austin Taylor raised an objection to a resolution passed by the Lighting Committee that the Council should provide electric light, in competition with the electric supply company, within its own area. The committee, he said, had received from the Council powers to effect a possible and amicable arrangement for the purchase of the company's undertaking. The resolution he complained of, however, was passed before the committee had even given an intimation of their desire to open negotiations, and that course was neither straightforward nor businesslike. The deputy town clerk, knowing the policy of the Board of Trade in regard to these licenses, assured them that they had no chance of getting one, and that if they did they would have to face a serious financial obligation, because the capital had to be repaid within seven years. The case they had to put before the Board of Trade was that they were supposed to negotiate with the company in a friendly way, and at the same time they were applying for a license to compete with them. He moved that the proceedings of the committee be approved with the exception of the resolutions of the 14th and 21st January, and that the Lord Mayor be requested to countermand the summons for a special meeting of the Council on the 6th March, under the Electric Lighting Acts. Mr. Petrie seconded the amendment, which was carried.

The City.—The past year's work of the City Commission of Sewers shows that the cost of electric lighting and the alleged surreptitious laying of telephone tubes by the City of London Electric Lighting Company were among the burning questions of the year. On May 1 it was pointed out that the 479 arc lamps in use cost £12,454 a year to maintain, against £4,631 for the 1,315 gas lamps which they have replaced. Since then proposals have been considered for a cheaper system than arc lamps for the side streets, but nothing was settled during the year. The telephone tube difficulty arose in this way. When it was discovered, the previous year, that the electrical company had laid telephone tubes along with their own mains, an agreement was come to that the placing of telephone wires in the tubes should be allowed on condition that the use of the telephones should be granted to persons in the City at £8 a year, including all the latest conveniences and improvements. The New Telephone Company was to have had the use of the tubes by arrangement with the electric lighting company, but when the National Telephone Company averted the threatened competition by absorbing its rival and annexing the contract for the tubes, it refused to make use of them on any such condition as the £8 rental. In these circumstances Mr. Gordon moved on July 17 that the £8 agreement should be rescinded, and that the Commission should accept an offer of the electrical company that on consent being given to the use of the tubes they would pay 10 per cent. of all rentals received up to £10,000 and 20 per cent. on rentals in excess of that sum, the minimum payment to be £1,000 a year. There was a majority in favour of this motion, but it failed to secure the support of the two-thirds necessary in a rescinding resolution, and was accordingly lost. On July 31 Mr. Pannell moved a simple rescinding resolution as to the £8 condition, which was refused by the company, and this was carried, it being pointed out that the refusal of terms simply led to the multiplication of overhead wires. This left the ground open for further negotiations, but no fresh steps have been taken since, and the tubes apparently lie fallow pending a working agreement. The new Commission held their first meeting on Tuesday. Mr. Wallace asked what had been done by the Streets Committee in respect to the use of electric conduits for telephones, and whether the Commission was justified in refusing to accept the large revenue offered by the company for the use of the electric conduits for telephonic purposes. The Chairman said the matter was under the consideration of the Streets Committee, which would report shortly. Mr. Burmester explained that Mr. Morton considered that the present question and that of the Post Office agreement were bound up together, and so no report had yet been made to the Court, but he (the speaker) could hardly see how the two questions were so closely connected. He believed the committee would present a report on the subject at the next Court. The discussion then closed.

South Staffordshire Tramways.—Major Marindin, of the Board of Trade, has attended at the Town Hall, West Bromwich, for the purpose of holding a conference with the representatives of the various local authorities in the Black Country with reference to the use of steam on the South Staffordshire tramways. Major Marindin explained that the conference was held with reference to the extension of the license for the use of steam upon the Staffordshire tramways. Some of the authorities, he understood, objected to that extension being given. He thought it would be better to ask the tramway company what their proposals were with regard to the matter, and what length of time would be necessary for them to have to enable them to introduce some other system of traction which would be satisfactory to the local authorities. Mr. Blundstone, director, said the company were at present involved in expensive litigation, and until that was settled they were not in a position to introduce any other system of traction. He thought that in six months' time their affairs would be considerably straighter, and they might be able to introduce a new form of traction. With regard to the new form of traction, he pointed out that the cable system was the most expensive, and if it was to be laid down as far as Carter's Green from Handsworth it would be four or five years before it would pay. They had provided the public with a great convenience for many years without having a farthing profit. There might be an inconvenience through the use of steam, but unless it was dangerous he thought the local authorities might very well extend it until the tramway company was in a more flourishing and stable position. If the company cabled the line from Handsworth to Carter's Green, the rest of the line would be worked with overhead electric traction. If the extension were granted, the company would be in a position to see where they were. He estimated that the cost of cabling the line from Handsworth to Carter's Green would be about £70,000. He denied that the line worked by the overhead system of traction was under the control of the Electric Construction Corporation, although he admitted that they paid the latter about 8d. per mile, or about four-fifths of the receipts per mile. The Electric Construction Corporation owned the generating stations and cars. The present directors did not recognise the contract because they believed it was ruinous to the company. Mr. A. Dickenson, manager of the company, estimated that the cost of laying down the cable system from Handsworth to Carter's Green would be at least £70,000. He said he did not know what the intention of the present directors was, but the late directors intended to lay down a cable system from Handsworth to Carter's Green. They did not, however, know the satisfactory working of the electric system, and they assumed that it would be more costly than the cable system. At that time it was possible to make arrangements with the Birmingham Central Company to run the cars right through to Birmingham from Carter's Green, and terms were practically arranged; but internal discussion arose, and the persons who were willing to find the money would not now do so. The cost of laying down a cable system was very great, and during construction it would cause considerable inconvenience to the public. He did not think there would be any difficulty in arranging for money to equip the lines electrically, but there would be a difficulty in getting the money to lay down a cable system. If the electrical system was adopted in West Bromwich, they would require arms about 10ft. in length They could then arrange to run cars direct from Walsall and Bloxwich to West Bromwich without changing. They had no complaints from the local authorities through whose districts the electric system passed, but, on the other hand, it was approved. Not only had the line in the Walsall district given entire satisfaction, but it was worked freer from accidents than any other tramway in the kingdom. The mayors of Wednesbury and Walsall had written to him congratulating him upon the satisfactory working of the electric system. It could be worked about 3d. per mile cheaper than steam. Ultimately the inspector promised to report the matter to the Board of Trade, and afterwards inspected the line.

PROVISIONAL PATENTS, 1895.

JANUARY 28.

1915. **An electric safety alarm indicating fog-signalling apparatus for preventing accidents on railways at junctions, stations, and level crossings, and for other purposes.** A. Tylee, J. Miles, and G. F. Nightingale, 3, St. John's-place, Castle-street, Kingsland, London.

1931. **Making carbons, candles, and pencils for electric lighting and parts of electrical machines or dynamos, such as "brushes," out of plumbago, graphite, or blacklead in its natural state.** Wolf Henry Cohen, 118, Fenchurch-street, London.

1936. **Improvements in or connected with dynamos.** Jesse Graham and Harry Chapman, 33, Chancery-lane, London.

1940. **An improvement in electrical controlling switches.** Edward Hopkinson and Arthur Pemberton Wood, 28, Southampton-buildings, Chancery-lane, London.

1949. **A combined mat and electric alarum contact.** James John Pye, 27, Martin's-lane, Cannon street, London. (Complete specification.)

1954. **Improvements in and relating to electrical devices, such as electromotors, generators, and the like, for use in explosive atmospheres.** Sidney Allingham, 1, Queen Victoria-street, London.

JANUARY 29.

1970. **A method of and apparatus for charging electrical accumulators from alternators and changing into an alternating current the current given by the accumulator cells.** Joaquin de Galindez, 46, Lincoln's-inn-fields, London.

2004. **Improvements in electric recording meters and in motors for operating same and for operating the escapement mechanism of clocks or other apparatus requiring a chronometric movement.** Benjamin Joseph Barnard Mills, 23, Southampton-buildings, Chancery-lane, London. (Charles Wirt, United States.)

2009. **Improvements in holders for electric lamps.** William McKenzie and John Ambrose Fleming, University College, Gower-street, London.

2025. **Improvements relating to combined gas and electric light standards.** Robert Walter Braham, 76, St. Agnes's-place, Kennington, London. (Complete specification.)

2031. **Improved automatic coupling for electrometers.** Siemens Bros and Co, Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.) (Complete specification.)

2064. **Improvements in automatic switches and in their use for distribution of electricity.** John Hopkinson, 5, Victoria-street, Westminster.

JANUARY 30.

2077. **Closed-conduit electric railway.** Edward James Paterson, European Works, Pownall-road, Dalston, London. (F. F. Atkinson, United States.)

2100. **Improvements in the construction and method of arrangement and connection of cables and joints for electrical distribution.** George Schults, 6, Lord-street, Liverpool.

2133. **Improvements in or relating to electric batteries.** Junius Pogneaux, 323, High Holborn, London.

2134 **Improvements in or relating to electrical signalling apparatus for preventing collisions between trains.** Alejandro Basanta y Baqué, 323, High Holborn, London. (Complete specification.)

2137. **A permanently and automatically synchronised printing telegraph.** Charles Austin Beck and Charles Rock, 106, Great Russell-street, London.

JANUARY 31.

2182. **A duplex incandescent electric lamp.** George Frederick Attree, 8, Hanover-crescent, Brighton.

2218. **Improvements in or relating to "watt-hour" counters for alternating currents of electricity.** Georg Hummel, 323, High Holborn, London.

2223. **Improvements in and connected with phonographs.** George McMurdie and Christopher Daggett, 4, South-street, Finsbury, London.

2228. **An improved combined starting, reversing, and controlling electric switch for operating electric motors.** Walter Angrove Clatworthy, 1, Queen Victoria-street, London.

2237. **Improvements in induction coils for use as resistances in electrical plant working with alternating current and with multiphase currents.** Josef Franz Bachmann, Josef Liebscher, and Adolf Vogt, 46, Lincoln's-inn-fields, London.

FEBRUARY 1.

2250. **Improvements in double and triple pole switches.** Frank H. Starling, Gresham Electrical Works, Nottingham.

2277. **Improved method and means of connecting electrical accumulator plates with their conductors.** Georg Hirschmann, 31, Southampton-buildings, Chancery-lane, London. (Complete specification.)

2280. **Improvements in galvanometers.** William Oliver Smith and George Keith Buller Elphinstone, 5, South-row, Blackheath, London.

2288. **Improvements in voltaic batteries.** Desmond Gerald Fitz Gerald, 53, Chancery-lane, London.

2289. **Apparatus for counting or recording telephonic conversations.** John Edward Kingsbury, 24, Southampton-buildings, Chancery-lane, London. (The Western Electric Company, United States). Complete specification.)

2303. **Improvements in and relating to apparatus for lighting and extinguishing electric lamps.** Lucien Hermand, 45, Southampton-buildings, Chancery-lane, London.

FEBRUARY 2.

2308. **Improvements in apparatus for testing magnetic quality in iron.** James Alfred Ewing, Langdale Lodge, Cambridge.

2312. **Improvements in apparatus for regulating electrical pressure.** Job Thomas Niblett, 20, Devonshire-road, Greenwich, London.

2333. **Improvements in apparatus for the use of the electric light for photographic purposes.** Andrew George Adamson, 154, St. Vincent-street, Glasgow. (Complete specification.)

2341. **Improvements in the driving of electrical or other machines on railway or other vehicles or engines.** William Henry Hallsworth, Bow Mills, Dukinfield.

2343. **Improvements in or relating to electric incandescent lamps.** Augustus Edwin Pope, 6, Lord-street, Liverpool. (Frederick Roberts Pope, Holland.)

2355. **Improvements in magnetic testing apparatus.** William Edward Ayrton and Thomas Mather, Central Technical College, Exhibition-road, London.

2366. **Improvements in electro-dynamometers.** Siemens Bros. and Co., Limited, and Edward Friedrich Heinrich Hermann Lauckert, 28, Southampton-buildings, Chancery-lane, London.

2373. **Improvements in the socket joints of metallic telegraph poles.** Bullers, Limited, and Edward John Chambers, 7, Staple-inn, London.

NOTES.

South Africa.—Buluwayo and Salisbury are now connected by telegraph.

Joined in Parallel.—The marriage has taken place at the Fulham Parish Church of Mr. J. D. F. Andrews and Miss Amy Beatrice McKrill.

Electric Traction in Switzerland—An electric tramway is to be built at Zurich—from the chief railway station to below Wipkingen.

Electric Lighting in Austria.—The electric light is to be installed in the palace of the Archduke Karl Ludwig in Favoritenstrasse, Vienna.

Transcontinental Telegraph.—The Portuguese at Tete have agreed to utilise the Transcontinental Telegraph Company's standards for their wires, thus ending the dispute up there.

Pacific Cables.—In the Senate at Washington, Mr. Call urged that if cable communication was established between the Sandwich Islands and America, it would go far to counteract British aggression.

Sentence—A man named Patrick Finn was on Monday sentenced to five years' penal servitude for breaking into the warehouse of the London Electric Wire Company, Limited, Playhouse-yard, St. Luke's.

Electrically-Lighted Ambulance.—Mr. Robert Feilendorf has, for the Vienna Volunteer Ambulance Corps, installed the electric light inside and outside two ambulance wagons. The arrangement is giving satisfaction.

Underground Conduit System.—A new underground conduit system for electric tramcars has been devised by the Hoerde Bergwerks and Hütten Verein. Illustrated particulars are given in the *Elektrotechnischer Anzeiger* of 10th inst.

Students of the Institution.—A students' meeting of the Institution of Electrical Engineers will be held in the library of the Institution, 28, Victoria-street, on Friday next, the 22nd inst., at 8 p.m. Mr. E. C. Hoadley will read a paper on "The Efficiencies of Dynamos and Motors, and their Measurement."

Lecture.—Prof. Kennedy, the consulting engineer of the Edinburgh Corporation, was to have lectured last week on the electric lighting of Edinburgh to the members of the Edinburgh Literary Institute. He was, however, prevented by indisposition from attending, but Mr. Monkhouse, the resident engineer, read the lecture.

Northern Society of Electrical Engineers.—The ballot for new members on Monday last resulted in the election of the following: Messrs. W. F. D. Duncan, of Wigan; A. B. Mountain, of Huddersfield; John Platt, of Roubaix, France; R. O. Ritchie, of Leeds; R. Shaw, of Manchester; and Chas. Turner, of Salford.

Institution of Electrical Engineers.—An extra meeting will be held by kind permission of the council of the Society of Arts at their rooms, 18, John-street, Adelphi, W.C., on Thursday next, the 21st inst., at 8 p.m. The following paper, by Dr. John Hopkinson, M.A., F.R.S., past-president, will be read: "Propagation of Magnetism in Iron," illustrated by experiments.

Waterloo and City Railway.—A suggestion was made to this company last week by Mr. Archibald Scott, who recommended that a station should be constructed on the north side of Blackfriars so as to tap the extensive traffic in that neighbourhood. The directors decided to consider the suggestion. The work of constructing the railway is being carried on night and day.

Economical Working of Arc Lamps.—In our issue of November 23, 1894, we described a mechanical device brought out by Messrs. Hardtmuth and Co., of Vienna, for ensuring economy in the consumption of arc lamp carbons. We now note that *L'Energie Electrique* of February 1 describes a similar arrangement for use both with direct and alternating current arc lamps.

London-Paris Telephone Service.—The Postmaster-General, in answer to Mr. Henniker Heaton in the House of Commons on Tuesday, said that during business hours the telephone between London and Paris was in constant use, so that there could be no doubt there was a demand on the part of the business classes for such communication. He could not see his way to reduce the rate for a three minutes' conversation from 8s. to 3s., as had been suggested.

Personal.—Two of Prof. Jamieson's assistants at the electrical engineering laboratory of the Glasgow and West of Scotland Technical College have just received appointments. One, Mr. William Murray Morrison, has been chosen by the British Aluminium Company, Limited, to assist them in their manufacture of aluminium by the electrolytic process. The other, Mr. David A. Ramsay, has been elected, out of about 100 candidates, to be an electrician at Helsby, in the works of the Telegraph Manufacturing Company, Limited.

Royal Meteorological Society.—An ordinary meeting of this society will be held at 25, Great George-street, Westminster, on Wednesday next, the 20th inst., at 7.30 p.m. The following papers will be read: "Report on the Phenological Observations for 1894," by Mr. Edward Mawley, F.R.Met.Soc.; "The Thunderstorm and Squall of January 23, 1895," by Mr. William Marriott, F.R.Met.Soc.; and "On some Gradual Weather Changes in Certain Months at Greenwich and Geneva," by Mr. Alexander B. MacDowall, M.A., F.R.Met.Soc.

Electric Lighting in Madras.—A new department is being opened at Madras by Messrs. P. Orr and Sons, of that town. According to the *Indian Engineer*, the firm intend to more particularly apply themselves to the best known methods of artificial illumination, with kerosene lamps, gas, and electric light. If the electric light is desired, a Crossley Otto gas-engine will be fixed for the operation of a dynamo. Messrs. P. Orr and Sons are agents for the Otto gas-engine and the Crompton dynamo, together with the manufacturers of all the fittings and accessories.

New French Cables.—According to a *Times* correspondent, the "François Arago" has left Calais with the 260 miles of cable manufactured by the Société des Téléphones, and will stop at St. Tropez to take in the 200 miles of cable contracted for by M. Grammont. These cables will be laid between Majunga and Mozambique, where a connection will be made with the cable of the Eastern and South African Company. "It is deplorable," remarks a Paris journal, "to be forced still to use English cables. It proves the vital necessity for our country to extend the system of French cables."

Electricity and Water Power.—Recognising the increasing attention now being paid to the profitable utilisation of water power, Messrs J. P. Hall and Co., of Blackriding Ironworks, Werneth, Oldham, have issued a new price-list of turbines and dynamos. The illustrations show dynamos direct coupled to turbines, and the advantages of using water power are clearly indicated. The construction of the Girard turbine is represented in cross-section, together with a brief description, and illustrations of the Jonval turbine are also given. Complete details of the

Digitized by Google

horse power of these turbines for different falls will be found in the list.

Proposed Pacific Cable.—Matters in connection with the proposed Pacific cable have progressed so rapidly recently that Canada has submitted a proposal for the appointment of a joint commission, to meet in England, to discuss the details of the project. It is suggested, a *Times* correspondent says, that the commission shall consist of three representatives—one of Great Britain, one of Canada, and one of Australia. A telegram from Washington on Tuesday states that the Bill for the incorporation of the International Pacific Company to lay a cable between California, Hawaii, and Japan has been introduced in the House of Representatives.

New Mains.—The Highways Committee of the London County Council have approved of the application of the House-to-House Electric Light Supply Company to lay mains in High-street, Allen-street, and Abingdon villas, Kensington, but decline to allow a transformer-chamber to be used. The same company will also lay mains in Drayton-gardens, Philbeach-gardens, and Earl's Court-road. Approval has been given to applications by the Westminster Electric Supply Corporation to lay mains in Birdcage-walk, Queen Anne's-gate, Regency-street, Carey-street, Fyne-street, Dorset-street, and across Vauxhall Bridge-road, and by the Notting Hill Electric Light Company to lay mains in Holland-park.

European Glow Lamp Manufacturers' Union.—The quarterly meeting of this union has been held at Vienna. It was reported that the objects and regulations of the union had proved not only of great utility to the firms associated therewith, but also to the whole electrical industry, and it was decided to maintain the union. Expectations exist that the French manufacturers of incandescent lamps will join the body. The establishment of a black-list had, it was stated, proved of value. A communication was received from the Electrotechnical Society of Vienna suggesting that the manufacturers should establish a code of normal conditions, and Mr. Johann Kremenesky was deputed to go into this matter with the committee of the Electrotechnical Society.

Municipalisation of Tramways.—The Highways Committee of the London County Council reported on Tuesday that, in response to their advertisement inviting tenders for the lease of the portion of tramways about to be transferred to the Council, they had only received one offer, and that was from the London Street Tramways Company itself. The term of the lease was to expire on December 31, 1900, and the company offered to pay an annual rental of £5,729, but there was a doubt as to the company's power to take a lease. Taking into consideration all the circumstances of the case and the absence of competition, the committee thought the company's offer reasonable, and recommended its acceptance, conditional upon the company's obtaining powers to take a lease. The Council adopted the recommendation.

The Government and the Telephone Companies. The Postmaster-General, in reply to Mr. H. C. Morton in the House of Commons, stated that he had received deputations from the London County Council and the Association of Municipal Corporations on the subject of the agreement with the telephone companies, and he was glad to think that those interviews had removed some of the objections or misapprehensions which were felt as to the effect of the agreement. The agreement merely embodied the heads of the arrangement signed by his predecessor in 1892, in accordance with the report of the Select Committee of the House, and with the policy approved by Parliament in the Telegraph Act of that year. Under these circumstances the Government did not consider that there would be any advantage in referring the matter to a fresh committee.

Party Walls.—The Tribunal Civil de Périgueux have just decided that a party wall is the co-proprietary of two neighbours without either of the two being able to claim the exclusive proprietary of any portion of the wall. Thus it follows that a third party cannot utilise the wall without the consent of both of the proprietors. It appears that the local electrical company, having obtained permission from M. Brachat to put up iron standards for the accommodation of electrical conductors on a party wall separating the latter's premises from those of M. Delpal, carried out the work. Thereupon M. Delpal brought an action against the company, and in deciding the case in the sense indicated by the opening lines of this note, the Court ordered the company to remove the standards and condemned them in costs.

Elevated Railways.—Several schemes for elevated railways have been brought before the German public lately. One by Mr. Eugen Langen, to which we have previously referred, and which he is trying to introduce in Berlin, consists of a single row of columns, each having a T-piece, which supports the superstructure. The carriages are suspended from vertical wheels which run along this superstructure, the whole being sufficiently high to clear the carriages from obstructions in the streets. A modification of this system has been worked out by Messrs. E. Dietrich and H. Müller, professors in the Royal Technical High School, Berlin. Their structure is considerably lighter, and the wheels are placed in almost a horizontal position. Both plans, particulars of which appeared in a recent issue of the *Elektrotechnische Anzeiger*, of Berlin, bear a resemblance to the American Boynton "Bicycle" railway.

Taxation of Machinery.— A meeting of members interested in the Rating of Machinery Bill took place at the House of Commons on Wednesday week, for the purpose of settling the form in which the Bill on this subject was to be introduced in the current year, and to make the necessary arrangements for promoting its success. Among the members present were: Sir William Houldsworth (in the chair), R. G. C. Mowbray, H. Smith-Wright, W. H. Holland, H. J. Roby, Gerald Balfour, W. E. M. Tomlinson, E. Strachey, M. Oldroyd, W. Mather, and W. Coddington. It was announced that a large number of members had intimated their intention to take part in the ballot for places, which in the usual course is held at the commencement of every session, and after careful consideration it was decided to introduce the Bill in the form in which it was brought before the House last session. As the result of this ballot yesterday week, Mr. Gerald Balfour was again fortunate in securing the third place upon the list of private members' Bills, and the supporters of the Bill therefore commence their campaign this session with excellent prospects.

Street Explosions.—The *Lancet* has gone somewhat out of its way to deal with this matter under the somewhat sensational heading of "The New Street Danger." The conclusion which our medical contemporary comes to is that "a time will probably come when electrical engineers will find themselves in practical agreement as to the best and safest systems of laying underground electric lighting mains, but in the meantime existing systems have to be dealt with. It is evident that underground electric mains, culverts, and boxes constitute in some instances reservoirs of considerable capacity for an accumulation of escaping coal gas, which, unmolested and ever increasing, only awaits the electric spark or arc or red-hot conductor, or the lamp of the workman or a discarded match, to

Digitized by Google

determine its explosion. The means of minimising this kind of danger by ventilation, drainage, insulation, and attention to the construction of street boxes with a view to the reduction as far as possible in their capacity, are sufficiently well known. And searching enquiry should follow all such accidents. But it may also be suggested that inspection might materially diminish the frequency of their occurrence."

Transformer-Chambers in London.—The Highways Committee of the London County Council on Tuesday reported as follows: "On 29th January we reported, in connection with the orders applied for by the County of London and Brush Provincial Electric Lighting Company for power in (*a*) Battersea, (*b*) Newington, and (*c*) St. Olave's district, that we had under consideration the question of suggesting to the Board of Trade the expediency of provisions being inserted limiting, if not prohibiting, the adoption under any one of the orders of a system of supply which would involve the construction of transformer-chambers of large size in the public streets. We have since been informed that there would be little value in such a provision as that indicated above, as no system of supply necessarily involves the placing of transformer-chambers under the streets; but, to attain the end we have in view, we now recommend, that it be suggested to the Board of Trade that the following words be inserted in each of the orders above referred to: 'Provided always that nothing in this order shall be held to authorise the undertakers to construct, in or under the surface of any public street or place, chambers or receptacles for transforming apparatus of greater span than 3ft. and more than 2ft. 6in. in depth.'"

"Universal Electrical Directory."—The 1895 edition of this well-known directory (J. A. Berly's), which has established a very high reputation throughout electrical circles, has just been issued, at the price of 4s., by Messrs. Alabaster, Gatehouse, and Co., of 22, Paternoster-row, E.C. The "red book," as it is now generally termed, occupies one of the most prominent positions in the branch of trade directories. The present issue, which contains the names of the members of the electrical and kindred industries throughout the world, has been thoroughly revised, and the British alphabetical section now comprises about 9,168 distinct names; the Continental section, 6,490; the American section, 3,922; and the Colonial section, 1,378, being a total of 20,958. This number embodies approximately 2,500 names of individuals and firms more than were contained in the previous edition. The directory, for simplicity and facility of reference, is divided into four groups—namely, British, Continental, American, and Colonial—which are again subdivided into alphabetical and classified sections. Apart from the new names incorporated in the present edition, much financial information has been added, the telegraphic addresses and local telephone numbers are given, and the total pages added to the work are 80 as compared with that of 1894, making, in all, about 866 pages entirely of directory matter. This directory is indispensable to the electrical trades.

Electric Locomotives for Mines.—The great advantages accruing through the adoption of electric locomotives in mining operations is exemplified by a letter which the Acme and Immisch Electric Works, Limited, of Queen-street-chambers, E.C., and Chalk Farm, N.W., have received from Mr. W. H. Borlase, the manager of the Greenside Mining Company, Limited, of Greenside, Patterdale, Westmoreland. In the course of his communication the writer says: "You will be pleased to hear that our electric locomotive has just completed 6,000 miles of running, with an average working load of 20 tons, at a cost of only £12, and this for renewing the training wheels, which have just been replaced. The wearing of these can be to a great extent accounted for, seeing that some of the gradients are equal to 1 in 20, necessitating a heavy brake being applied occasionally. The electrical part of the locomotive has required no repairs whatever, the armature and commutator apparently are as good as at the first, and the latter has never been turned up since it left your works. Taking into consideration the exceedingly sharp curves and their frequency in the line of rails, to say the least, the wear and tear is really surprisingly low, and does great credit to the workmanship on the machine. In fact, the whole of the extensive electrical plant you have supplied us is in splendid working order, doing good duty, and has from its erection (now three years) proved thorough efficiency at an infinitesimal working and repairing cost. We look upon the work accomplished by the locomotive as marvellous, it having far exceeded our expectation in ability and cost of maintenance."

Testing, Mathematical, and Telegraphic Instruments.—It is scarcely necessary to say that almost throughout the world the testing and telegraphic appliances made by Messrs. Elliott Bros., of 101 and 102, St. Martin's-lane, W.C., are to be found in daily use; whilst at the same time their electrical, optical, engineering, and mathematical apparatus have been largely adopted by the English and other Governments. The instruments manufactured by the firm are also used by the Board of Trade, London County Council, and important standardising laboratories, and by electric supply companies, and in colleges and universities in all parts of the world. It is now some time since Messrs. Elliott Bros. issued a new catalogue, but they have now done so, and the copy lying before us is an elaborately illustrated production of some 150 quarto pages. It would be impossible to more than briefly enumerate the very large variety of instruments referred to in the catalogue, but there may be taken as a fair sample: galvanometers of various types and shunts, lamps, scale stands and scales for reflecting instruments, standard resistances, Wheatstone bridge coils, Lord Kelvin's rheostats, sets of resistance coils, portable testing sets, electrometers, keys and switches, standard cells and accessories for use with testing apparatus; telegraphic instruments of all kinds, chronographs and other recording instruments, drawing apparatus, length-measuring appliances, goniometers, spectroscopes, Lord Kelvin's standard balances, photometers, etc. In fact, the catalogue deals with every kind of instrument required in a telegraph office, college, laboratory, or central station.

County of London Company.—Subscriptions are invited for a first issue of 10,000 6 per cent. cumulative preference shares of £10 each at par, and a further issue of 10,000 ordinary shares of £10 each at 5s. per share, in the County of London and Brush Provincial Electric Lighting Company, Limited, which was registered in June, 1891, for the purpose of undertaking the supply of electricity in certain districts in the county of London, and elsewhere in the United Kingdom, where capital may be profitably employed in electric supply. In March, 1894, an issue of 19,900 ordinary shares of £10 each was made and fully subscribed, making with 100 shares previously subscribed a total issue of £20,000 shares, but an official quotation has not been obtained, as, according to the rules of the Stock Exchange, no such quotation can be granted until one-half, at least, of the capital of the company has been offered to the public. The directors have therefore resolved to comply with the requirements of the Stock

Digitized by Google

Exchange and to provide for the development of the company's business by offering the present issues of preference and ordinary shares. It is intended that future issues of preference shares shall be made only at a premium. The directors consider that the earnings of the company during the present year will be amply sufficient to pay the amount required for dividend on the present issue of preference shares. In the prospectus issued in March, 1894, it was stated that provisional orders, confirmed by Acts of Parliament, for the following districts in the county of London had been obtained: the united parish of St. James and St. John, Clerkenwell; the parish of St. Luke, Middlesex; the district of the Wandsworth Board of Works, including portions of Putney, Clapham, Balham, Upper Tooting, Tooting, Brixton Hill, and Streatham Hill; and the parish of St. George-the-Martyr, Southwark. Since then, considerable progress has been made with the works. In London, sites have been secured for power stations for St. Luke's, Clerkenwell, and Wandsworth, and the laying of mains and other necessary work has been energetically carried on. Plant for the supply of 90,000 8-c.p. lamps is in course of manufacture, and it is expected that the supply of current in these three districts will be commenced from the company's stations in the autumn of the present year. The company is also associated with the stations at Bournemouth and Dover, and with the Windermere project. The list will close at 4 p.m. to-day (Friday). The address of the company is 49, Queen Victoria-street, E.C.

The L.C.C. and Telephones.—On Tuesday the Highways Committee of the London County Council reported as follows: "The Council on 3rd October, 1893, referred it to us to consider how far the proposed agreement about to be made between the National Telephone Company and the postal authorities would affect the Council's position in regard to the telephone service in London, and we were at the same time authorised to confer with the Postmaster-General on the subject. Proceeding upon this reference, we looked very carefully into the provisions of the agreement; and we soon came to the conclusion that, if the agreement were carried out, the interests of the people of London in the matter of telephone service would be to a great degree prejudiced by the power given under the agreement to the National Telephone Company, whose existing monopoly would be further strengthened. Moreover, we did not find in the agreement any provision or arrangement for reduction of charges, a matter of grave importance to the business people of London. We therefore came to the conclusion that one of three courses should be taken—namely (*a*) that severe restrictions should be placed upon the company; (*b*) that the State should take over the company's business; or (*c*) that the municipality—*i.e.*, in London, the Council—should do so. We requested the Postmaster-General to hear us by deputation, which he did on Monday, the 4th of February. The Postmaster-General stated that the agreement was practically entered into between the Government and the telephone companies in the year 1892, but that he had consistently maintained in the negotiations with the telephone company that the company has no monopoly, and that the Government is perfectly free either to carry on the telephone business itself or to give powers to other licensees. He did not, however, appear to think that the Government would be able to give facilities for a long discussion in the House of Commons, although some discussion might take place. In view of the answer of the Postmaster-General, we think that every effort should be made to obtain some modifications of the agreement before it is finally ratified, and it occurs to us that this object would be best attained by the agreement being referred for consideration by a Select Committee of the House of Commons; and we may say that the Commissioners of Sewers of the City of London have passed a resolution to this effect, and have sent a copy of it to the Postmaster-General as well as to the Council. We recommend that the London members of Parliament be requested to ask for the appointment of a Select Committee of the House of Commons to make full enquiry into the proposed agreement between the Postmaster-General and the National Telephone Company, and the relation of such agreement to the powers and duties of municipal authorities in London and elsewhere."

Municipalisation of Telephony.—The deputation representing the Town Councils of Glasgow, Edinburgh, and Aberdeen, who waited upon Mr. Arnold Morley in London on Monday for the purpose of urging that they should be granted licenses for carrying out municipal systems of telephones, and that the draft agreement with the National Telephone Company should not be confirmed, did not receive much consolation. In the course of his reply to the deputation Mr. Morley remarked: "I am a great believer in the municipal government system in this country, and with regard to all matters which can be distinctly shown to be matters with which municipalities can effectively deal, I should be the last man in the world to turn a deaf ear to any such suggestions. But the Government have to look at this matter from a different point of view. You have come to press on the Government that this matter should be treated as a municipal matter, but I wish to point out that the Association of Municipal Corporations in England have come to an entirely opposite decision. They put in the forefront of the case that the telephone system ought to be treated as an Imperial matter, and not as a local matter. If we once begin a system of municipal telephones, it is very difficult to say how far it would be possible to put a stop to it. My own belief is that the State must ultimately have complete control. This agreement does not prejudice that question at all. The only effect of this agreement, substantially and practically, speaking, is that the State should take over the trunk-wire system. The Government have suggested a scale of charges for the trunk-wire system. It is not exactly identical with that of the National Telephone Company, but I understand the latter, having made certain charges for trunk wires which are somewhat below what would be the charges on the Government scale, have intimated that the time is very shortly coming when, if the system is continued, they will have to revise the scale, as it is not sufficient to cover the cost. When the Government have control of the trunk-wire system, the municipalities would be able to bring pressure to bear on the Government to bring the charges down to a reasonable amount much more effectively than if the trunk wires remained in the hands of a company. Therefore, I do not think the telephone-using public are likely to be damaged by the fact of the Government taking over the trunk wires. Something was said about the creation of a monopoly by this agreement. I can assure you that there is no foundation for anything of the kind." In reply to further questions, Mr. Morley said he had no power to transmit the right of appeal to a licensee, and he would not do it if he could. He could not consent to an enquiry by a parliamentary committee which would reopen the whole question as to the trunk wires, but he would consult his colleagues as to the propriety of appointing a committee to enquire as to the working of the system in towns and as to the charges to come, and before which the corporations would lay their case.

THE ELECTRICITY WORKS AT BLACKBURN.

General Remarks.

The county borough of Blackburn contains an estimated population of about 126,000 inhabitants with a ratable value of £441,111, and the Corporation, as a progressive municipal body, are the owners of the gasworks, waterworks, markets, cemetery, free library, public baths, technical school, and two public parks, whilst at the same time the borough has its own quarter sessions. The staple trade of the town is cotton spinning and weaving, there being no less than 1,279,346 spindles and 66,335 looms.

The Corporation, in common with other corporations and local authorities, found it advisable in 1890 to apply for and obtain a provisional order giving them the exclusive right to carry out the electric lighting of the town, as, had they not taken this course, there were public companies ready and willing to obtain the necessary powers and to undertake the electric lighting of the town.

As there is a profit to be made out of electric lighting, the Corporation prefer that whatever profit there is to be made should be applied in the relief of the rates. After careful consideration by the Gas Committee, to whom the question of electric lighting was referred by the Town Council, it was decided to adopt a site at the No. 1 gasworks for the erection of the station, and part of the gasworks buildings was made available for the purpose. The necessary alterations to these buildings were carried out under the superintendence of Mr. Samuel R. Ogden, the borough gas engineer, at a trifling cost.

It was considered all the more advisable by the committee to adopt this site because it appears pretty certain that in the future, after the present gas-making plant at the No. 1 works has been worn out and becomes superseded by more modern appliances, it will not be desirable to continue the gasworks at that site, and consequently there will be ample room for future extensions of the electric light station.

A report and estimates of the installation were submitted to the Gas Committee of the Corporation by Mr. Thomas Barton, electrical engineer and contractor, carrying on business in Blackburn, and on his recommendation a low-pressure direct-current system was adopted, and the station has been erected.

The contracts for the steam and electrical plant were placed with the following firms:

Messrs. Yates and Thom, Blackburn, boilers, steam-pipes, pumps, etc.	£2,330
Messrs. Siemens Bros., Limited, London, steam-engines and dynamos	4,820
Messrs. Siemens Bros., Limited, switchboard	770
Electrical Power Storage Company, London, accumulators	2,150
Messrs. Siemens Bros., Limited, cables (not including excavation, etc.), junction, feeder, connecting boxes, etc.	5,860
Messrs. Doulton and Co., London, stoneware insulators	350
Messrs. Ashton, Frost, and Co., Blackburn, iron culverts	3,000
Messrs. Ashton, Frost, and Co., steel junction-plates for culverts, at 6s. 6d. per cwt.	550

Blackburn.—Map Showing Route of Feeders, Distributors, and Feeder Points.

The excavation of the streets for laying the cables, the making good, and all brickwork in connection with the feeder and junction boxes were also carried out under the superintendence of Mr. S. Ogden.

In September, 1894, the Town Council having decided to obtain further advice, Mr. E. M. Lacey, A.M.I.C.E., of 19, Old Queen-street, Westminster, was retained as consulting engineer to the Corporation during the erection of the electric lighting installation. Messrs. Siemens Bros. commenced the laying of the cables at the end of last September. It was originally intended to supply consumers on a portion of the system by the arrival of Christmas, but owing to certain delays and to the recent frosts, the progress of cable-laying has been impeded, and the opening of the station has thus therefore been retarded down to the present time.

Digitized by Google

The System Adopted.

In December, 1894, as the works were so near completion, the Council considered it advisable to advertise for a resident electrical engineer to take charge, with the result that Mr. A. S. Giles, A.I.E.E, formerly of the Edison-Swan Company, was appointed, having been selected from amongst a large number of applicants. Mr. Giles has accepted an appointment from the Committee of the Blackburn Technical School, with the sanction of the Corporation, and will conduct for the special benefit of apprentices and workmen engaged in electrical work a course of practical instruction, which promises to be of great value to the town and district generally.

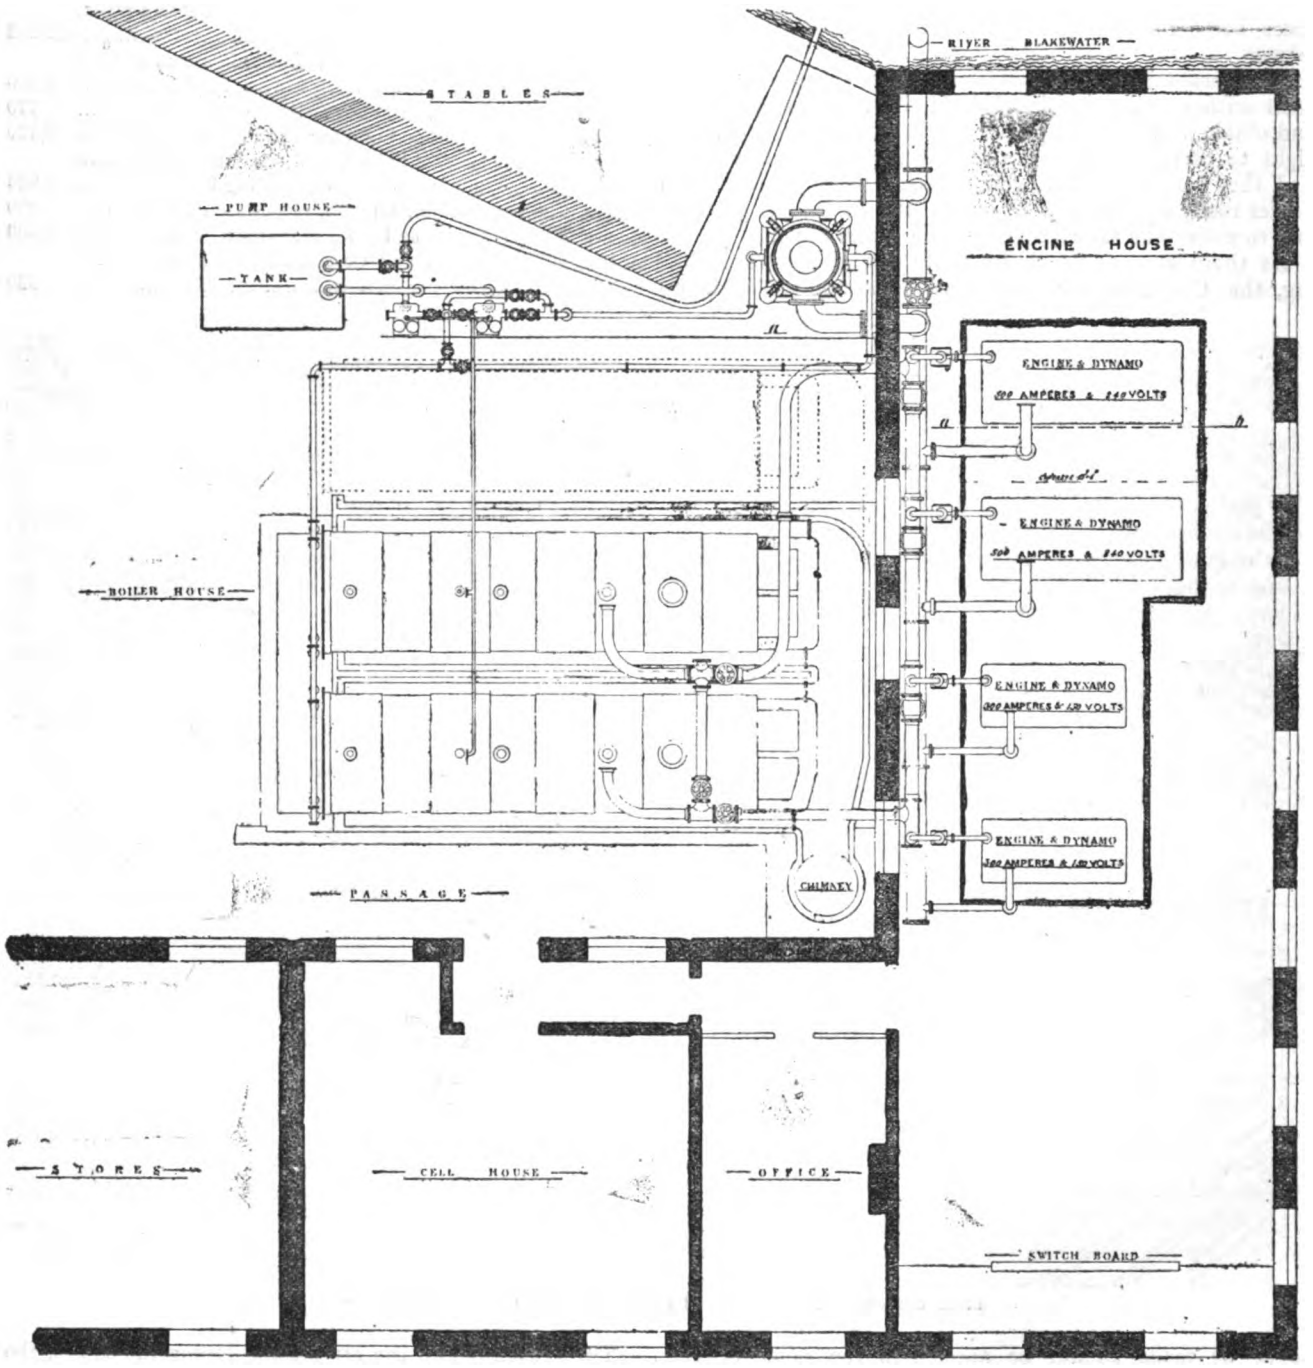
So far as the system adopted is concerned, there is little that is novel, the method being direct-current and low-pressure distribution on the three-wire system. The works were designed with a view to supply the principal streets in the centre of the town, as shown on the annexed map.

The works are situated in Jubilee-street, and adjoin the Corporation gasworks. The buildings comprise engine and boiler houses, accumulator, meter, and engineer's rooms, and stores. The boiler-house is at present of a temporary character. The engine-house is 87ft. long by 24ft. wide, which allows ample room for any extensions of the machinery which may be required at the present works.

The Boilers.

At present two Lancashire boilers are fixed, and accommodation is provided for a third boiler, which will shortly be placed in position. The boilers were made by Messrs. Yates and Thom, of Blackburn. They are 28ft. in length and 7ft. 6in. in diameter. Each boiler has two internal flues 3ft. in diameter, and is fitted with four Galloway tubes. The boiler mountings throughout are by Messrs. Hopkinson, of Huddersfield. The boilers, which are constructed for a working pressure of 120lb. per square inch, are equipped with Proctor's mechanical stokers, which are driven by a small electric motor supplied by Messrs. Siemens and Co.; and Meldrum's furnaces, made by Messrs. Meldrum Bros., of Atlantic Works, Manchester, have been adopted.

Amongst other advantages claimed for the Meldrum furnaces are—economy in steam raising; that by the employment of forced draught, cheap fuels, such as coke breeze or other waste fuels, can be utilised; and that the power of the

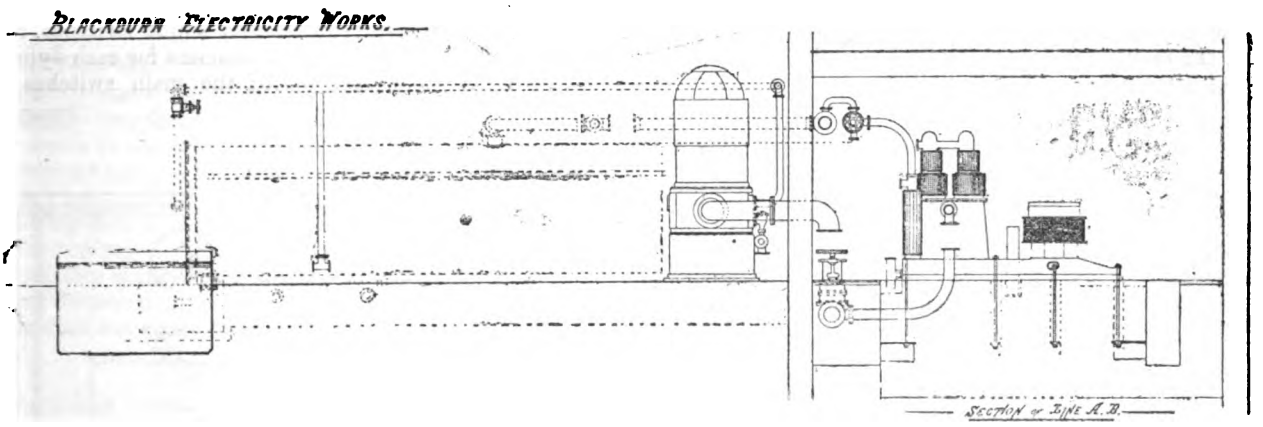


BLACKBURN ELECTRICITY SUPPLY STATION

Blackburn.—General Plan.

Digitized by Google

boilers can be increased to much beyond that obtained by the employment of natural draught, except by means of a somewhat costly edifice. Therefore, it should be possible to put down fewer boilers to meet the maximum load, and in cases of emergency these furnaces are capable of rapidly increasing the rate of combustion to meet any sudden demand for steam that may arise at a central station through fogs or other causes. This system, it will be remembered, has been adopted with great success in many central stations.

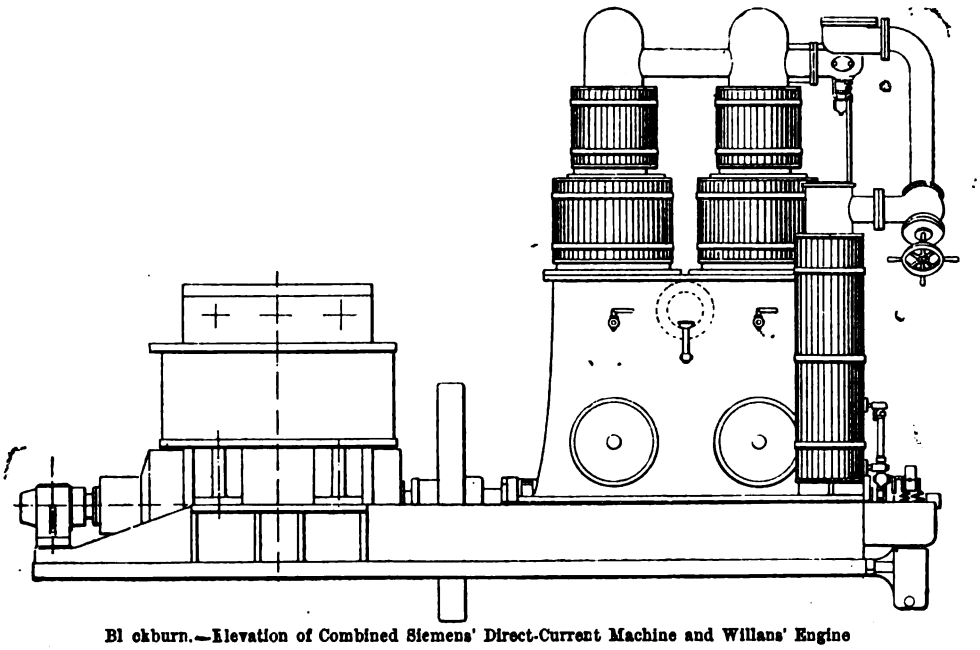


Blackburn.—Cross-section through Boiler and Engine Houses.

The water supply is obtained either from the River Blakewater or from the Corporation mains, and a storage tank has been provided holding about 2,000 gallons. From this tank or from the river the water is drawn by two Worthington vertical marine-pattern pumps, each capable of delivering 4,000 gallons per hour, and fed into the boilers through an improved exhaust-steam feed-water heater.

It is through this heater that the exhaust steam from the engines is passed for the purpose of heating the feed-water supply to the boilers. This heater, which has been provided by the Patent Heater Condenser Company, of 16, Great George-street, Westminster, London, S.W., is of the company's No. 14 special type for electric light stations, made extra strong for a working pressure of 120lb. per square inch, and capable of raising the temperature of 3,000 gallons of water per hour to 200deg. F. by means of exhaust steam only. The heater is 13ft. high and 5ft. 5½in. square at the base, and is fitted with an arrangement by which the casing can be raised with the smallest amount of labour, there being only one point to break, so that the whole of the internal tubes are very easily accessible for inspection or cleaning. The water inlet and outlet connections are on the cast-iron body of the heater and not on the casing, as in the ordinary heaters. The casing is therefore left entirely free for removal by the new arrangement. The casing is 54in. in diameter, and is made of mild-steel plates planed on the edges and hydraulic riveted. The exhaust steam inlet and outlet are 20in. in diameter, and all the internal tubes are of best solid-drawn brass and copper. The heater is also fitted with the company's new wrought-iron bottom for the prevention of back pressure.

The system of steam-piping is clearly shown in the general plan of engine and boiler houses. It is arranged in a ring form, valves being provided to allow of any portion being cut out without interfering with the supply to the engines. The main steam-pipes are of wrought iron, with wrought-iron flanges, the tee pipes being of cast iron. They are suspended from the walls of the engine-house by means of rods and brackets, allowance being made for expansion. The bends and branches to the engines are of copper. Suitable arrangements are provided for draining the sections of the steam-pipes.



Blackburn.—Elevation of Combined Siemens' Direct-Current Machine and Willans' Engine

The main exhaust-pipe is of cast iron 12in. diameter, and is carried as shown on the plan, branches being provided for the purposes of forming a way either through or by the heater.

Steam-Engines and Dynamos.

Four compound engines, made by Messrs. Willans and Robinson, of Thames Ditton, of the Willans central-valve type, have been put down, the dynamos being mounted on the engine bed-plates and direct driven. Two of the engines are of the Willans II. type, and the other two are of the G.G. type. The guaranteed efficiency is 22½lb. of water per indicated horse-power.

Digitized by Google

The dynamos are by Messrs. Siemens Bros., and are of their usual central-station type, with drum armatures, the field coils being shunt wound. The two larger machines have each an output of 500 amperes at 240 volts, with a speed of 330 revolutions per minute, and the two smaller machines each have an output of 300 amperes at 150 volts, with a speed of 450 revolutions per minute.

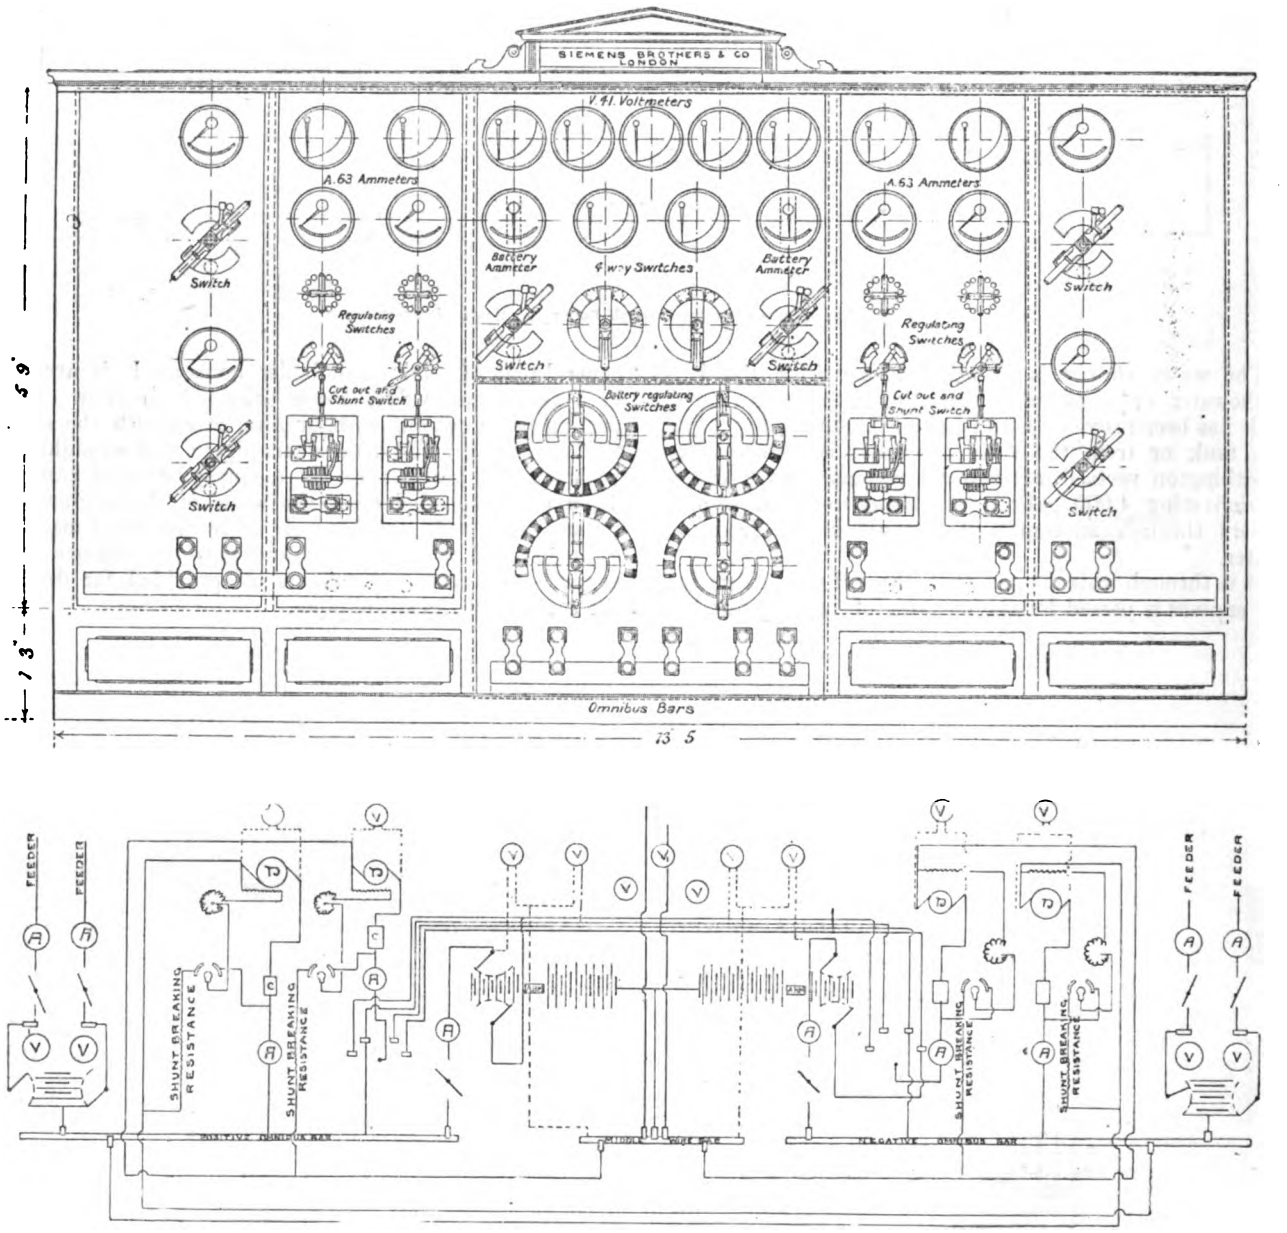
The guaranteed efficiencies of the combined engines and dynamos are as follows: for the large sets, 82 7 per cent. at full load, and 72 8 per cent. at half load; for the small sets, 79 2 per cent. at full load, and 68 per cent. at half load.

The engine and dynamo plant has been put down to meet the requirements of the current supply for the equivalent of 10,000 8-c.p. lamps installed.

The Switchboard.

The switchboard is situated, as shown on the plan, at the north end of the engine-house. The general arrangement of the switchboard is represented and the connections are shown in the annexed elevation and diagram.

The board consists of five panels of enamelled slate. On the centre panel are placed the battery regulating switches, the battery ammeters, voltmeters, and two four-way switches for the small dynamos, so that either of these dynamos can charge on to either side of the accumulators. The panels on either side of the centre panel contain main automatic cut-out and shunt switches, regulating switches, ammeters and voltmeters for each dynamo. On the outer panels are placed the main switches and



Blackburn.—Elevation of Switchboa and Diagram Connections.

Accumulators.

These consist of 120 cells, each containing 87 K-type plates, arranged in three sections of 29 plates each, connected in parallel, and made by the Electrical Power Storage Company, of 4, Great Winchester-street, London, E.C. These cells are capable of giving a discharge of 300 amperes at 240 volts for 3½ hours, or on an emergency are capable of discharging 850 amperes for one hour. The containing boxes are of lead with insulated bottom, and provided with lips to prevent electrical leakage due to creeping of the acid. The cells are placed on varnished wood trays on glass oil insulators. All connections are designed with a view to prevent undue rise in temperature when the batteries are discharging at their maximum.

ammeters for the feeders. On these panels, also, the feeder regulating switches will be placed.

The leads from the dynamos and accumulators are brought on the switchboard to omnibus bars, which are capable of being regulated to any required difference of potential. From these bars, feeders are taken to the feeder points. Each feeder will be provided with additional independent regulation by means of regulating switches and counter E.M.F. cells. The output of the station is measured by means of Thomson's watt-hour meters attached to each feeder. The whole of the switches, instruments, and apparatus on the board were made and supplied by Messrs. Siemens Bros., Limited. Mr. Vincent was in charge for that firm of the whole of the station work.

Digitized by Google

The Mains.

The cables have been supplied by Messrs. Siemens Bros., of London. They are very highly insulated with pure and vulcanised rubber, and have been laid on stoneware insulators in iron culverts. These insulators were made by Messrs. Doulton and Co., of Lambeth, S.E. At present the feeders from the station on to the distributing network are only two in number, each having a cross-sectional area of ·8 square inch for the outer cable and ·5 square inch for the inner. The cables for the distributing network are of three sizes, having cross-sectional areas of ·5, ·3, ·5 square inches, ·4, ·3, ·4 square inches, and ·25, ·2, ·25 square inches respectively.

The tests taken before any house services were connected up came out after two minutes' electrification at over 1,500 megohms per statute mile, a matter of considerable credit to the contractors, taking into consideration the difficulties they had to contend with. Mr. Horn, A.I.E.E., was in charge of this work for Messrs. Siemens Bros.

The services to consumers are vulcanised rubber cables laid in iron pipes. These services are carried to terminals immediately within the consumer's premises, at the expense of the Corporation, provided that the distance from the mains does not exceed 60ft.

Public Lighting.

The public lighting already sanctioned consists of four arc lamps at Sudel Cross, two arc lamps in front of the Town Hall, and two in front of the Market Hall, also two on Salford Bridge, and two at the corner of Church and

Blackburn.—Feed-Water Heater.

Darwen streets, making 12 lamps in all. They are made and supplied by Messrs. Siemens Bros., and are arranged on standards furnished by Messrs. McFarlane and Co., of Glasgow.

Of course, when the Corporation have experienced the advantages of arc lamps for street illumination they will, as has been carried out in other towns, considerably extend their use in the principal thoroughfares. It is not a question of expense, but one of improving the lighting of the main streets to the benefit of the general community.

Private Lighting.

Distributing mains have been laid, and a supply of electrical energy is available in Church-street, Darwen-street, Lord-street, New Market-street, King William-street, a portion of Preston New-road, Richmond-terrace, Library-street, Exchange-street, Victoria-street, etc.

Already upwards of 3,000 lamps have been applied for, and this number does not include the Town Hall, Municipal Offices, etc. Further applications are being received, and it is hoped that the present station will soon be working at its full capacity.

The charge made by the Corporation for electrical energy is at the rate of 7d. per Board of Trade unit, or, say, a little more than the cost of gas in the town at 3s. 7d. per 1,000 cubic feet. But when the incidental advantages of electric light are taken into consideration—a more healthy illuminant, one which does not detrimentally affect wall papers, ceilings, curtains, books, etc., and one which, if judiciously used by the consumer by the aid of switches, is economical—it will be found that a better light is obtainable for the same money as gas.

The consumption of electrical energy will be registered by meters, the rental of which will be from 2s. 6d. per quarter, according to the size of the meter. Then for those who desire to use electric power the charge will be only 5d. per unit.

The Corporation will lay the service wires between their mains and the consumer's premises. They will only bring these lines into the consumer's premises at the point nearest to their service manholes, and will fix the end of their mains into a cut-out box. The consumer's wires must be brought out as far as the Corporation cut-out box, and the ends left ready for sweating in, which will be done by the Corporation. Where the service line required is not more than 20 yards in length from any distributing main of the Corporation, it will be laid free of charge to the consumer's meter; where the length of service line required is more than 20 yards, the additional length of service line will be laid at the cost of the consumer.

Conclusion.

The Corporation are to be congratulated upon having established municipal electricity works. In fact, as they have municipalised water and gas, it would have been a pity to have permitted the electric lighting of the town to have been undertaken by a company. Even the tramcars bear the title of the "Corporation Tramways Company," and the Municipality might do well to favour the adoption by the former of electric traction, and dispense with the unsightly steam cars which grace (!) some of the Blackburn streets. The best wishes of all will be for the success of the electricity works which are now on the point of being officially set in operation. But before concluding, one or two remarks are necessary in regard to two gentlemen in the town.

Notwithstanding the services rendered by the chairman of the Gas Committee (Alderman Thompson) and the town clerk (Mr. Robert E. Fox), the public have reason to be grateful to the Gas Committee as a whole for the intelligent and business-like manner in which they have devoted themselves to this important work.

Mr. Alderman Thompson has spared neither time nor trouble to make the undertaking a complete success during the progress of work; the town clerk also rendered valuable service, and it has been a great advantage to the Gas Committee and a valuable saving of time to have had the benefit of experience and advice such as Alderman Thompson and the town clerk were able to contribute.

RULES FOR INSTALLATION WORK AT BLACKBURN.

The Blackburn Corporation have drawn up the following rules and regulations for the guidance of contractors and consumers:

Wiring.—No system of wiring involving connection to earth of one of the conductors will be allowed to be connected to the Corporation mains. The mains from the Corporation cut-out boxes should be taken to distribution-switch and cut-out boards, and should there be divided into as many small circuits as practicable, each circuit being protected by a cut-out on each pole and governed by a switch. These small circuits should carry no more than five amperes. Where conductors pass through walls or behind plaster they should be run in porcelain or iron tubes, and no joints should be made on them. When conductors pass through party walls, separate porcelain tubes must be used for each conductor. Also when conductors pass through walls dividing one fireproof compartment from another they must be enclosed in separate porcelain tubes. External conductors will not be allowed unless the method of fixing, general arrangement, etc., has first been explained to the electrical engineer and received his approval. Any conductors that are run on, or in the immediate neighbourhood of, or fittings that are secured to, structural ironwork, pipes, or any parts of the building having good connection to earth must be specially well insulated, and efficient means taken to prevent accidental contact. No disused circuit is allowed to be left with the current on the conductors, but should be cut off on both poles close to the mains. In theatres and all buildings such as are considered hazardous risks by the insurance offices, special precautions must be taken, such precautions varying according to the nature of the hazard. All work inside houses is to be carried out in strict accordance with the rules of the fire insurance office in which the building and contents are insured.

Digitized by Google

Conductors.—Each conductor shall be of such a sectional area that the current in it shall not exceed 1,000 amperes per square inch, and of such area with respect to its length, that the fall of pressure between the point where the conductors of the Corporation are connected with the installation and the furthest lamp therein shall not exceed 2 per cent. The sectional area of any conductor carrying over 100 amperes must not exceed the ratio of 750 amperes per square inch. All conductors of a larger sectional area than No. 16 S.W.G. should be composed of strands, no conductors of less size than No. 18 S.W.G. should be used except in fittings, and in fittings no conductors should be of less size than No. 20 S.W.G. All conductors must be made of copper of a conductivity not less than 98 per cent. of that of pure copper. Each conductor must be tinned. The ends of all stranded conductors must be solid soldered before being fitted into any cut-out or switch. Concentric conductors will only be allowed under those circumstances and in those places for which permission has first been obtained, and when the particular system and design proposed has been previously approved by the electrical engineer.

Insulation.—The insulating covering of all fixed conductors must consist of at least one coat of pure indiarubber, one coat of vulcanised indiarubber, braided and compounded to preserve the insulation from mechanical injury, and the said insulating coverings must be of such quality and thicknesses that the insulation resistance of any conductor shall not be less than 600 megohms per mile. Should it be desired to use any material other than vulcanised rubber, samples must be submitted to the electrical engineer to the Corporation before the work is commenced, and must receive his approval. Flexible wires must be insulated with vulcanised rubber to 600 megohms as above.

Joints.—All joints to be well and neatly soldered, resin only being used as a flux. All joints in the insulation to be covered with at least six laps of pure rubber, the braiding, cotton, or tape being cut away on either side of the joint, leaving the insulating material and copper conductor to be covered with pure rubber. When this has been done the whole to be covered with protecting tapes, each layer to be soaked in indiarubber solution. No joints to be made in conductors that are buried in casing or tubing in walls.

Casings.—All casings must be composed of sound, hard, and well-seasoned wood. The conductors must be kept apart by a continuous fillet, which should not be less than 1½in. wide in the case of the mains, and not less than ½in. wide in that of the smallest branches. All the covers to be firmly screwed with brass screws fixed in the outer edges of the casings, and on no account in the centre fillet. All casings are, wherever practicable, to be run along the surface, but when it is necessary to sink them into the plaster the casings are to be well painted inside and outside with two coatings of good oil paint. In every case the casings must be painted inside with fireproof paint. Under no condition whatever must staples be used for fastening down conductors.

Cut-outs or Fuses.—All fuses are to be of approved pattern, mounted on suitable incombustible material. A double-pole cut-out must be placed at every change of section of wire, and the fuses must be of such section, length, and nature, that they will fuse and disconnect the circuit if the current passing through exceeds the normal current by 50 per cent. All fuses should be in places easily accessible, and be stamped with the current at which they will fuse. Every cluster fitting or lamp of higher than 16 c.p. must be provided with a double-pole fuse.

Switches.—A double-pole switch and cut-out must be provided and fixed directly at the point of attachment to the Corporation mains, or in such other place as may be determined by the electrical engineer. No metal parts of switches which are in connection with the circuit should be left exposed. All sectional switches must be of good design and mounted upon non-combustible bases, with covers of same material or of metal, and must be arranged so that they do not turn on, at one time, more lamps than require a current of 10 amperes.

Branch Circuits.—Each installation (unless by special permission of the electrical engineer) must be divided into circuits carrying not more than 10 amperes each—that is, current equal to supplying 20 16-c.p. lamps.

Fittings.—All lamp fittings to be well and substantially made, special care to be taken to avoid injury to the conductors contained therein. All fittings as far as possible to be insulated at the base. No fitting to form part of the electrical circuit. Where combination gas and electric fittings are proposed to be used they must first be submitted to and approved by the electrical engineer, and the fittings must be electrically disconnected from the gas supply pipe by means of insulating flanges and bushes.

Three-Wire System.—All installations of more than 100 lamps of 16 c.p. or their equivalent must be wired on two main circuits for connection to both sides of the three-wire system. The two circuits should be made as nearly equal in capacity as possible. In any installation requiring a large and variable supply of current for lighting or motive power, the Corporation reserve the right to supply at a pressure of 220 volts, with subdivided circuits of 110 volts each.

Insulation, Resistance, and Testing.—On receipt of notice at the office that the work is ready, the Corporation will send their inspector, who will make one test and examination free of charge. Before the test is taken, all switches must be placed on and all fuses must be inserted. Should the test be satisfactory, the inspector will then examine the installation to see that all the lamps light. If it should be found that the installation is not ready for testing, or if it fail to pass the test, a fee of 10s. must be paid for each subsequent test before such test is made. Notice in writing should be given to the Corporation, at their office, Jubilee-street, by the wiring contractor at least 48 hours before a supply is required to be turned on, and the contractor must send his representative at the time fixed to give any information concerning the installation that may be required. The Corporation will not supply current to any installation under any of the following conditions: (*a*) if there are any temporary wires or fittings; (*b*) if the work is not carried out in accordance with the rules already stated; (*c*) if the whole of the work is not completed and all fittings fixed; (*d*) if, when testing with a pressure of 110 volts, the insulation resistance to earth is below the following standard—50,000,000 divided by the number of lights installed.

Example.—For an installation of 25 lights the insulation resistance must be $\frac{50,000,000}{25} = 2$ megohms.

WATER-POWER INSTALLATIONS FOR ELECTRIC LIGHTING.

BY E. R. DOLBY, WH.SC.

The reader of technical literature dealing with the subject of the application of water power for the purpose of electric lighting must have been struck with the tone of sorrow in which various writers from time to time deplore the want of judgment of British engineers. They instance the successful use of large and small powers in Switzerland for similar purposes, and though bound to admit that there is in England no great scope for the use of waterfalls, they still appear to think that this source of energy is neglected.

It may be worth while considering what are the advantages in actual practice of the use of water power. There are, so far as the writer is aware, only two practicable sources of energy of this class: (1) that of a flowing stream, (2) that of a distinct fall of water.

(1) Numerous attempts have been made to make use of the energy in flowing water. The author some years ago made experiments upon a floating motor which was moored in the Thames for test purposes. This apparatus consisted of a pair of floating vessels, between which were placed a series of blades *en echelon*; these blades were fixed to a chain which passed over the driving wheels on the deck of one of the vessels. The flowing current acted upon the surface of these blades, and as the chain was endless, some blades passed into the water at one end as others rose out of it at the other. The results, so far as efficiency was concerned, were decidedly disappointing, for with a current flowing at a rate of from 2½ to 2¾ miles per hour the brake horse-power developed by a machine which cost close on to £700 was little over 1 b.h.p. The price was, however, somewhat excessive owing to the novelty of the construction.

That the energy of flowing streams can be caused to produce rotary motion is obvious, as this type of motor is used in such rivers as the Tagus, the Rhine, etc., for grinding corn. So far, however, as the author is aware, the efficiency of these motors is very low, and though it may be raised possibly by more careful study of the most desirable form of blades, the size of the machines must always be very considerable for the power developed. The author's opinion is that such motors can only be of practical use where the current flows at a speed of at least four miles per hour, where the obstruction of such an apparatus in the channel is not objectionable, and where the water rental is very trifling or absent altogether.

(2) The second method—that of using a waterfall—appears at first sight very enticing. A country gentleman may have upon his estate a stream which either falls over a natural obstruction, or one having such a rapid fall in its bed that it lends itself to artificial means of producing a fall.

It is well in cases of this kind to have some instance in view. Upon a certain estate known to the author, a small stream ran down a narrow and steep ravine—the volume of the stream was, however, not very considerable. The owner of the estate was brought into communication with a firm of contractors, and they told him that his project to light his house by means of electricity was perfectly feasible, and that the small stream alluded to above would supply the necessary energy. Upon this assurance they secured the order to carry out the work. As there was no natural waterfall, it was found necessary to impound the water, and this was done at a point some 200 yards away from the house. Before obtaining the order, the contractors had remarked to their client that the works neces-

Digitized by Google

sary to make use of the water power were but trifling and would cost, say, £100, but that the owner would be able to do this work himself much more cheaply than his contractors. It may be observed that no consulting engineer had been employed, but that the contractors were left to their own sweet will.

Originally a simple earth bank across the ravine was proposed to impound the water, and it was suggested that a wooden conduit should be fixed to suitable trees on the route, so that the water could be carried along a horizontal plane and arrive at a point over the course of the stream where the requisite fall could be obtained. It is needless to add that the work had to be done in a more substantial manner. Owing to a series of errors, the levels were wrongly taken, and the necessary fall could not be obtained without excavating for the tail race through rock to a depth of some 14ft. A turbine was then installed and geared by belting to a dynamo placed in a small shed above. The expense incurred by the owner of the property in constructing the dam across the ravine, forming the wooden channel, and excavating the tail race was about £700, or seven times that suggested by the contractors as the probable cost.

Let us now see if the results have been such as to compensate for the initial expense. The water supply is totally inadequate, as the water used by the turbine is vastly in excess of that supplied by the stream to the reservoir; in fact, even in very wet weather there is not sufficient water to drive the dynamo sufficiently long to do the necessary work.

Here, then, is a clear case in which a large expense has been incurred without any adequate result. A secondary battery is installed at the house which could be charged during certain hours, when there was sufficient water, and discharged to effect the lighting of the premises.

In such a case as this it would have been far preferable to have put down an oil-engine close to the house. The plant, as it stands, has given light to the house possibly for three hours a month since it has been put down. The hurry to get hold of work at any cost, and to put in a price which is in appearance low, seems to induce certain contractors to undertake impossibilities. Because a mountain stream appears in wet weather to give a considerable volume of water, they are led to promise the production of energy exceeding by perhaps 10 times the possible output. The result must necessarily be disappointment to both parties and great injury to the electrical industry generally, besides serious loss of status to the contractors themselves.

Even supposing there be on the average sufficient water power to keep the plant running, it is practically impossible to make use of it at such a season as we are now passing through; the reservoir is frozen over and is useful for skating parties, but it is impossible to use the plant at all. To put down an oil-engine or a steam-engine as a stand-by, is to duplicate the whole plant and double the cost; and it therefore appears very undesirable to hurry into the proposal of the use of water power for comparatively small outputs without very carefully weighing the *pros* and *cons*. The fact that water power is present without any rental to pay, appears often to blind people to the difficulties in the way of applying it.

To the amateur engineer nothing appears easier than to use the energy of the tides, of running streams, and other sources of Nature, but the great cost of the permanent works in many cases raises a practical obstacle to the successful carrying out of such undertakings.

INSTITUTION OF ELECTRICAL ENGINEERS, Feb. 14.

MR. R. E. B. CROMPTON (President) in the chair.

At last night's meeting of the Institution the following candidates were balloted for:

Foreign Member.—Julius Martin, 16, Oak-street, Newark, New Jersey, U.S.A.

Associates.—Nigel Harington Balfour, 36, Cranley-gardens, London, S.W.; George Sydney Flood, 17, Delafield-road, Old Charlton, S.E.; W. E. Groves, 49, Hagley-road, Edgbaston, Birmingham; Alfred Ingram, Durham-road, Seaforth, Liverpool; Alfred Jacob, 50, Parliament-street, S.W.; Gerald Graham Palmer, Barton-under-Needwood, Burton-on-Trent; Walter Pethybridge, 183, King's-road, Chelsea, S.W.; Percival John Pringle, "Moringside," High View-road, Sidcup; Henry Walker, 11, Oxford-terrace, Gateshead-on-Tyne.

Students.—Bruce Charles Bouquet, 54, Graham-road, Dalston, N.E.; Frederic William Close, May Lodge, Leytonstone-road, Stratford, Essex; Walter James Coles, Finsbury Technical College, Finsbury, E.C.; Henry Thomas Constable, 105, Portobello-road, Notting Hill, W.; Urban Baly Gilbert, 3, Culverden-gardens, Tunbridge Wells; Ernest Herbert Lanham, City and Guilds Technical College, Finsbury, E.C.; Charles Histerman Merz, 38, Portland-street, Lincoln; Henry Joseph Norton, Finsbury Technical College, Finsbury, E.C.; Harold Yarington Packard, Finsbury Technical College, Finsbury, E.C.; Archie Corbet Seaton, Seaton House, Humber-road, Westcombe Park, S.E.; Harold Langton Tyson-Wolff, 166, Victoria-street, S.W.; Frederick Morier Walker, Faraday House, Charing Cross-road, W.C.; Frank Wilson, 162, High-road, Lee, Lewisham.

The following paper was then presented:

Reversible Regenerative Armatures and Short-Air-Space Dynamos.

BY W. B. SAYERS, ASSOCIATE.

The subject of the present paper is the development of the commutating device for continuous-current dynamos which I had the honour of bringing under your notice two years ago, and which has since been put into practice to a considerable extent by Messrs. Mavor and Coulson, of Glasgow, and other firms. It will be remembered that in my former paper I described a machine the armature of which generated its own field, the usual field magnets being replaced by simple C-shaped iron blocks, which Lord Kelvin, on viewing the machine, at once appropriately called "keepers." This property of a generator armature, when commutated on the backward lead, of producing or augmenting, as the case may be, the effective magnetic flux may, I think, be correctly described as a regenerative property, and I therefore propose to call armatures capable of being so commutated "regenerative armatures."

REVERSIBLE REGENERATIVE ARMATURES.

It was found that in many cases it was a serious drawback to machines constructed with regenerative armatures on my plan that they could only be run in one direction; in other words, the device was not reversible without structural alterations in the armature. I found a solution to this difficulty, however, in the construction shown in two diagrams presented to the meeting. In these figures there are represented two sections of the main winding of a drum armature—a commutator coil, which is connected to the main winding at the junction between the coils mentioned, and a commutator blade. The direction of winding is the same in the two figures, but in the first the direction of rotation is represented as being clockwise, while in the second it is counter-clockwise. A little study of these two diagrams will show that the commutator coil acts in precisely the same way in whichever direction the armature rotates, the brushes being always set with a backward lead, so as to bring the side of the commutator coil which is behind the point of connection to the main winding under the edge of the flux horn. In both cases only one side of the commutator coil is operative, the other side being in a position in the interpolar gap where normally there is no effective field.

I do not propose on this occasion to take up time with a minute description of the action of this device, the action of the reversible form now described being substantially the same as the simple form described in my earlier paper. In a few words, however, I may say the effective part of the commutator coil is still well under the flux horn when the commutator bar to which it is connected comes into contact with the heel of the brush, while the commutator coil immediately preceding it, which is under the brush and momentarily carrying the full current, is just passing out of the field, and consequently is the seat of a weaker and rapidly falling E.M.F.; the result of which is that the current flowing from the main winding is rapidly transferred to the more backward coil, which is still in the strong part of the field, and so is the seat of maximum E.M.F. In this way a third commutator bar comes under the heel of the brush, the action already described is repeated, and so the commutation proceeds.

I do not know whether it has been generally noticed that a close analogy exists between the problem of sparkless commutation and the problem of preventing knocking in a high-speed engine. In the latter case the valve must have a certain amount of lap and lead in order to give a sufficient compression and put on the live pressure at the proper time to just bring to a stand the motion of the connecting-rod, piston, etc., at the moment the crank is on the dead centre, and to restart them in the opposite direction. Just as the inertia of the reciprocating parts of the engine must be overcome by the steam pressure and not by the crank action, so the reversal of the current direction of the armature sections against the self-induction (the electrical analogue of inertia) must be overcome by internal E.M.F.'s, and on no account by the make-and-break action of the commutator plates and brushes. I think the analogy between these two things is strikingly complete.

Digitized by Google

Auxiliary Devices.

In the simplest form of reversible machine only half the length of the commutator coil is effective in producing the reversal when the armature is running in a given direction. A means, however, of bringing both sides of each coil into operation was shown in a third illustration. In this case there is provided a pole-piece forming an extension of the flux horn, leaving a recess having an angular breadth approximately equal to, or a little greater than, the angular width of each commutator coil. The commutation is effected in this recess. It will be seen that the same action as has already been described takes place with regard to the part of the commutator coil which is behind the plane of commutation; but, in addition to this, the forward part of the coil next in front—in which the current is falling—has come under the polar extension, and as the field under this extension is of the same direction as under the main portion of the polar surface, while the coil is cutting it in an opposite sense, this coil is the seat of a back E.M.F. which operates against the current in this coil, and so assists in producing the reversal of the main armature section, which is in series between the two commutator coils under consideration.

In designing machines with a polar extension such as I have described, it must be borne in mind that, as the flux conveyed by the extension enters the armature at a point past the plane of commutation, it is non-effective in generating E.M.F. as it enters and leaves the armature on the same side of the plane of commutation; it must, therefore, be treated as leakage, and provision made for this non-effective flux in the cross-section of the field magnets.

Number of Segments in Commutator.

The necessity hitherto found for using a large number of sections in the commutator, and of resorting to duplex or triplex winding in the case of large low-tension machines, ceases to exist when machines are designed on the lines I am describing, and the number of segments is governed practically by the difference of potential it is advisable to allow between adjacent commutator plates. Of course, it would generally be inadvisable to reduce this number sufficiently to make the current undulatory to an appreciable extent, unless for machines for arc lighting.

That nothing is gained by using a large number of sections in the commutator is easily found from theoretical considerations, and is borne out by experience. Consider a two-pole drum armature having 24 coils in series generating the E.M.F.—that is, a total of 48 coils. If we use a 48-part commutator, the time occupied in the reversal of an armature section will be one-forty-eighth of the time of one revolution. If, however, we use a 24-part commutator, the time occupied will be one-twenty-fourth. The reversing E.M.F. will therefore be acting for twice the time in the latter case, as compared with the former. In addition to this, in the latter case the angular distance between successive commutator coils is doubled, so that the one which is going out of circuit is farther away from the pole-tip, and so well out of the fringe; so that the reversing E.M.F. (which is always the difference between that generated in the coil going out of circuit and the coil coming into circuit under the brush) is greater with the lesser number of segments. And, again, whereas in the first case the opposing self-induction is that of one main section plus two commutator coils, in the second it is only two main sections plus two commutator coils—that is, less than double; and then, most important of all, the rate of change is only one-half in the latter case of what it would be in the former. The reduction of the number of bars in the commutator has the further advantage that it allows of the brushes bearing on a larger arc of the commutator surface, so that a smaller width of brush is necessary. It would not do, however, to reduce the number of slots, or tunnels, in the armature, and put two coils in each instead of one, as this would have the effect of increasing the self-induction four times.

Design of Slotted, or Tunnel, Armatures.

Just as the steam-engine designer makes his reciprocating parts as light as possible consistent with strength, so it is worth while to so design the slots, or tunnels, in an armature as to get the least amount of self-induction, and this is to some extent antagonistic to other desirable features in short-air-space machines.

In the first place, in order to keep down the self-induction, the opening at the top of the slot should be as wide as possible, consistently with its not exceeding the limit where appreciable loss would occur through eddies in the polar surface of the field magnets. The width of this opening, as stated in my former paper, should not exceed one and half times the air-space. I usually make it about one and a quarter times. Next, the number of conductors in each slot should be as small as consistent with considerations of cost of manufacture, though, as already shown, it is advantageous in many cases to make the number of commutator blades as small as possible—the conductors in two or more pairs of slots forming but one section of the winding. Some designs of slots which have given satisfactory results in machines made by Messrs. Mavor and Coulson were shown to the meeting. In one case was represented a plain slot with reversible commutator coils, the number of blades in commutator being equal to the number of slots in the armature core. There are thus two commutator coil wires and two main armature conductors in each slot. Of the two former, one only is in operation at a time, the second belonging to a commutator coil further back under the pole, and which has not yet come into circuit under the brush. In the second case was represented a slot having a groove planed near the top on each side, into which the round wire forming the commutator coil is slid. In this design the number of commutator blades is half that of the slots, and the alternate wires come into operation in succession, the wires intermediate between these belonging to commutator coils further back, and not in circuit for the time being. This design, in addition to advantages already pointed out, permits of the armature being a little smaller in diameter, and also requires no binding, the commutator coils effectively securing the main conductors in their position in the core. A construction adopted in an 80-kilowatt machine for direct coupling, the speed being 240 revolutions per minute, was shown to the assembly. This machine I shall describe later on. The number of commutator blades is one-half that of the slots, but equal to the total number of convolutions of main winding. Instead of the conductors at opposite potentials—*i.e.*, those connected at the time of commutation to the opposite brushes—being in the same slots as is the case in the other two figures, these are wound in separate slots, each convolution of the winding passing through slots which are one removed from being diametrically opposite. The result of this construction is that the self-induction of a main armature section is only about one-half of what it would be if there were two conductors in one slot, both undergoing commutation at the same time.

Parallel Running.

It is almost unnecessary to say that machines for running in parallel must not have a rising characteristic—at any rate, when combined with their driving power. I have made no experiment with direct-driven plants; but it is evident that if a combined plant running on the governors gives a falling characteristic, two or more such plants would run parallel, although the dynamo, when driven at absolutely constant speed, had a rising characteristic. Of course the characteristic is under the control of the designer, and, apart from questions of permeability of the magnetic system and relative magnetising powers of shunt and armature, depends upon the position of the plane of commutation relatively to the neutral plane.

The characteristic of an 80-kilowatt machine when driven at a constant speed was illustrated. This shows a rise up to 300 amperes, after which there is a gradual fall down to full load. If driven at a rigidly constant speed, or if coupled, or run from the same power supply, so as to both run at the same speed, two such machines would not run in parallel with safety. The characteristic, however, of the machine and engine combined, when the latter is running in its governors, was shown. The increase of speed with light loads is sufficient to transform the characteristic into a falling one, from which it results that two such separate plants would run in parallel perfectly. As I have already said, however, there is no difficulty about designing a machine to have a falling characteristic, even if driven at constant speed.

So far as my experience goes, there is not much inclination to run compound machines parallel in this country; but if it were desired to do so, the arrangement which suggests itself—a modification of the well-known method for machines with compound winding—was shown diagrammatically. There are two main brushes, set with a backward lead, and two small subsidiary brushes, set on the forward lead. Suppose one machine were started, and it were desired to connect the second one in parallel, the second machine would be started and its E.M.F. adjusted in the usual way; the small brushes on the first machine would then be put down; next, the two small; and after that the two sets of main brushes on the second machine. When connection is established between the two armatures at the four points and on the same side of the commutators, part of the current traversing the coils between the two planes of commutation will leave the first armature by the small brush and flow through similar coils on the second armature, just as the current from the series coils on compound machines splits up between the two series coils when they are first thrown into parallel in the well-known arrangement. The other brushes may then be put down and switches closed, when the small brushes on the forward position will give stability to the system, in the same way as the independent connection to the brushes keeps compound machines from any tendency to play into each other. Although I have not tried this arrangement, I think there is no doubt that it would work satisfactorily if it were desired to run machines with a rising characteristic in parallel. It is usual, however, in central-station work in this country to use shunt machines, and to control the current from each machine by means of a variable resistance in the shunt, and, no doubt, it will generally be pre-

Digitized by Google

ferred to use machines with a slightly falling characteristic for running in parallel, so as to avoid all complications. I may point out that with short-air-space machines considerable regenerative power is required in the armature in order to get even a moderate fall in the characteristic.

Rocking Brush-holders for Reversing Motors.

For reversible motors the fact of the regenerative armature requiring a forward lead, instead of a backward one, allows of a very simple and reliable automatic arrangement for shifting the brushes on reversal of direction of rotation. The rocking arm carrying the brush-holders is mounted on the shaft and suitably bushed and lubricated so as to move freely. The friction of the brushes causes it to be carried round with the armature until brought up by stops which limit its travel in either direction. These stops are, of course, adjusted so as to keep the brushes in the proper position for sparkless commutation. Thus, the position of the brushes is automatically changed without any sparking, as during the time in which the brushes are travelling from one position to the other immediately after a reversal they do not move relatively to the commutator, but travel round with it until brought up by the stops; so that there is no relative motion of commutator and brushes until the proper position is reached, and consequently no sparking.

Constant-Speed Motors.

The question has been put to me from more than one quarter whether motors fitted with regenerative armatures would be self-regulating—that is, run at constant speed with varying load when supplied with constant pressure at terminals—because the ordinary shunt motor owes its self-regulating qualities to the back turns in the armature, which have the effect of reducing the flux, and so compensating, so far as speed is concerned, for the increased drop of pressure caused by dead resistance in the conductors internal and external to the machine. The reply to this question is, that while in the case of generators it may be inadvisable to reduce the air-space below a given value on account of the crowding up of lines due to the large armature reaction causing a diminution in the total flux, and so bringing down the characteristic, in the case of a motor this action can be taken advantage of and the air-space reduced to a safe mechanical clearance: the reduction of the total flux due to crowding up will then tend to compensate for drop of pressure due to dead resistance. So that in the case of a motor we obtain the happy concurrence of lightest weight and minimum cost with best regulating qualities.

Description of 80-Kilowatt Dynamo built by Mavor and Coulson—420 Revolutions per Minute.

Armature.

Diameter over all	21in.
,, core	17⅛in.
,, hole in discs	4¼in.

Total flux (effective), N=20,600.000.

The main winding consists of 72 bars solid copper, 1·33 by 0·2in., connected at ends by "butterfly" connectors. Each bar is placed in a separate slot, and the connectors join the first to the thirty-sixth bar at each end. Thus the two bars in each convolution are one division less than diametrically opposite. In this case the commutator, or reverser, bar which is just under the pole-tip is joined at the commutator end to the commutator blade. At the distant end it passes over to the slot seventh removed, through which it returns and is joined to the main bar, which lies in the slot third removed from it.

Magnets.—The magnets are of (so-called) cast steel, and each half is made in two parts, with a division between them, ½in. wide, parallel to the magnetic flow, in order to reduce the crowding up of the lines from cross-induction—thus carrying out Prof. Thomson's suggestion.

The polar angle is	120deg.
The air-gap	¼in.
The shunt winding consists of 325lb. of No. 12 wire.	
Number of turns	2,016
Resistance at 120deg. F.	10·7 ohms.
Current	9·35 amperes.
Ampere-turns	18,800*.

The weights are as follows:

	Cwts.	qrs.	lbs.
Magnets, steel castings, etc.	35	3	2
Magnet coils	2	3	17
Armature (shaft, core, and commutator)	20	3	15
Windings, main coils, reverser coils	4	3	12
Bearing, rocker, brush-holders, etc.	3	3	1

The characteristic of the machine running at constant speed was shown, as was also the characteristic when the engine to which it was coupled was running on its governors. The engine was built by Messrs. Belliss, of Birmingham, and their test showed an efficiency of $\frac{\text{E.H.P.}}{\text{I.H.P.}} = 86$ per cent.

While this test was being made, however, the shunt coils were coupled in parallel, with a resistance in circuit which dissipated 1 per cent. of the total energy. So that the real efficiency of the combined plant is 87 per cent.

* This means 9,400 ampere-turns in each limb of magnets.

Discussion.

A somewhat new departure was made by the paper being taken as read The author then gave some observations with a view to demonstrating the advantages of his system, and he also explained at length the drawings and diagrams in connection with his paper.

Mr. Crompton moved a vote of thanks to the author, and, in doing so, said that they all appreciated the question of the air-space design. In the ordinary short air-space designs there was trouble with the commutators, and Mr. Sayers, he thought, justly claimed to have solved the difficulty.

Mr. Andersen said that he had not had experience in his own work of short air-spaces, and he had not had an opportunity of seeing Mr. Sayers's machines running. He thought, however, that there would be difficulties in connection with them, such as hysteresis and eddy currents in the field. He wanted to know if measurements had been taken as to these. If the plan of the author worked well it would be generally adopted, save where shunt machines were required. (Here Mr. Sayers explained that one of the machines illustrated was a shunt machine, and that no reversal took place even with a rising characteristic.) Mr. Anderson thanked Mr. Sayers for his valuable details, such as particulars of weight, etc. The weight of magnets, steel castings, armature, shaft, core, and commutator, etc., came to 64cwt. for a machine of, say, 96 per cent. efficiency. An ordinary horse-shoe type machine on the same lines would weigh for these items about 84½cwt, Mr. Sayers thus having a saving of about 25 per cent. But Mr. Sayers in other respects would have more weight, and his machine, he considered, required far more labour.

Mr. Mordey objected to the introduction by the author of new terms, such as "keeper," for field magnets, and "regenerative armature." If the armature were different from other armatures, he thought the best name to give it would be the Sayer's armature. Where the word "blades" had been used he preferred the old term, sectors. Mr. Sayers's was a clever arrangement for machines which had to run in both directions, but there were points of objection, such as sparking.

Mr. H. A. Mavor stated that the machines described were not experimental, but that they were quite successful practically in all the directions indicated. With regard to parallel working, he had taken the opportunity of being present at some experiments with the 18-kilowatt machine, which was represented in the diagram on the wall. As far as his experience went, no difficulty had been experienced in switching in parallel. In fact, the engineer where the tests took place used the expression that the machine was waiting for its load, which it took up very easily.

Mr. H. Ravenshaw, whilst admitting that there was great credit due to the author, thought that the latter put his extra copper in the wrong place. The author placed it on his armature, and that was a bad mechanical job. Since Mr. Sayers read his first paper, the speaker had made some experiments with what were known as cross-field dynamos, and to which he referred by means of diagrams. He had wound the cross-field coils so that he could separately excite them. He did so to a certain amount of load, and then varied the current in the cross-fields until the machine did not spark; and then till it did spark, and next below sparking, and got readings. As a result the machine was got to work so that it worked absolutely without sparking.

Mr. Horace Parshall referred to some experiments which had been carried out in the same direction as the author's. Two of the machines of 1,000 h.p. and 2,000 h.p. respectively, were shown successfully in operation at the Chicago Exhibition, and they worked entirely satisfactorily without sparking. With regard to the weights adduced by the author, whilst they in some respects showed a saving, he somewhat doubted whether he had demonstrated an economy as compared with some recently-designed machines. For instance, the weight of the armature seemed to be excessive, as was also that of the copper in the armature.

Mr. W. B. Esson said that he used to make slotted armatures, but so far from the clearance being ¾in., it was only ¼in., and there was no trouble through sparking. Looking at the question from the point of view of the manufacturer, he would like to know how the Thomson machines compared with the size of the ordinary machine. The author had not explained the 80-kilowatt machine—whether the magnets were of steel; if so, they were expensive. Another point that struck him was the difficulty which would be experienced in the making of different sizes of machines, necessitating a frequent resort to the pattern shop, and consequent expense. It seemed to him that the cost of connecting up the extra coils and providing for them must add considerably to the cost of the machine. He would like some definite information on the matter.

Mr. G. L. Addenbrooke referred to the experiments made with the 80-kilowatt machine at Belsize, and stated that many of the machines of that type were working satisfactorily.

Mr. C. C. Hawkins bore testimony to the efficiency of the 80-kilowatt machine. He submitted that it would be interesting to have placed before them the efficiencies of the machines at full loads.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

ELECTRIC WELDING.

Whatever may have been the chief causes at work in effecting the result, it will be admitted pretty generally that the art of electric welding has not made very rapid public development in this country, and even to-day it is to be feared that two-thirds of those engaged in the electrical industry have little or no acquaintance with the theory and working details of electric welding by either of the two accepted methods. Still less, therefore, will be the experience or knowledge of this art amongst mechanical engineers, although it would, and must, prove of immense advantage to the latter in almost every phase of their work. We propose, therefore, to emphasise in these paragraphs the importance of welding by means of electric currents, and to show how advantageous and economical the process may be in the workshop, factory, or steamship. As for the causes that have hindered the development of electric welding, we do not touch upon them more than to say that some of them have been very real, and others more fancied than actual. Over-capitalisation and other erroneous methods of promotion may be responsible for much of the delayed progress; but so far as the Benardos system of arc welding is concerned, it would seem as though the desire had been to hasten slowly, to make absolutely sure of each step, and to claim nothing which might not be certain of fulfilment.

To judge from the particulars contained in Mr. Foster's long and interesting paper upon this subject just read before the North-East Coast Institution of Engineers and Shipbuilders, and published on another page in this issue, the time ought now to be ripe for entire confidence to be felt in electric welding when properly applied; and we cannot refrain from hoping that the growth or extended use of these processes may henceforth in a natural fashion be as rapid and profitable as the electrical industry could possibly desire.

It is not, of course, postulated that welding may be done by electricity at a merely nominal cost. So far from that, the outlay not only upon the necessary plant, but in working expenses also, must be *apparently* very heavy; and we can feel no surprise at engineers hesitating with regard to the adoption of such a process when they are informed of the actual horse-power required to make a given weld. But it must not be forgotten that this energy is employed usefully—that instead of being spread over a considerable space of time under the ordinary system of heating in a furnace and welding under the hammer, the whole process is completed in a few minutes, and therefore the amount of energy increases in proportion. There is, no doubt, a saving of time effected, to begin with, in electric welding, and although large amounts of energy are required for the actual work of welding, yet this energy is not spent or wasted during intervals of work, as it must be to some extent with the ordinary process. Not only does the electrical plant give out just as much energy as is required, but every detail has been so studied that the efficiency by means of storage, etc., shall be very high, whether the plant

Digitized by Google

is being called upon or not. Although, therefore, it may seem costly to put down special plant of large capacity for welding purposes, the final result shows that an absolute and considerable economy is possible of easy attainment.

For special work of an intricate nature, where ordinary methods are practically unavailable, a process like that due to Dr. Benardos has many advantages. Its portability, or ease of application, should alone secure its adoption in numerous cases, as pointed out in Mr. Foster's paper. Take, for instance, a broken ship's crankshaft or propeller-shaft. Accidents of such a kind invariably require instant remedies, but the difficulties of repairing a screwshaft can only be realised by those who have had to work at huge masses of metal in a confined space. With a portable welding plant on board it should not be a matter of many minutes to suitably patch a shaft together so that easy steam may be kept up. The suggestion offered by Mr. Foster in his concluding paragraph with respect to a portable arrangement of this kind, moving from place to place for incidental work, is also of considerable value, and will doubtless be adopted. It serves, at any rate, to show the great range of application possible for such a system, whether ashore or afloat—for regular work or occasional repairs.

Coupled with the paper read some time ago by Mr. B. A. Dobson upon electric welding before the Institution of Mechanical Engineers, we are inclined to think that the particulars now given by Mr. Foster will serve to prove most conclusively that these processes are long past their experimental stage, and may now be relied upon for good and efficient as well as economical working.

KENSINGTON COURT STATION.

We regret to state that about 10 on Tuesday night a fire broke out in the offices of the Kensington Court central electric light station of the Kensington and Knightsbridge Electric Light Company. Unfortunately, a child of Mr. Holland, the resident foreman, was suffocated, but otherwise the circumstances are such that congratulations can be offered to the electricians concerned in the station. There was virtually no cessation in the supply of current, owing to the arrangements which had been made. There is another station at Chapel-street, Knightsbridge, which has not been directly connected with that at Kensington Court, though the connection could have been made in almost a nominal period had it not been for the severe frost, which prevented the connection-boxes being opened until they were thawed. Owing to the admirable structural arrangements of the Kensington Court station, the boilers and engines were saved, and the electrical supply was maintained. The accumulator-room was destroyed, and the fire was so fierce that the electrical engineers on the premises had to work under circumstances in which probably no central station has ever been run before. In fact, one of our representatives was informed that Mr. Crompton, who was fortunately at home at the moment in the neighbourhood, actually stuck to the switchboard until he was lapped by the flames. That consumers have not suffered by a large fire of this sort at a central electric light station shows the advantages of electric lighting over that of gas lighting. Had a conflagration of the same comparative magnitude taken place at a gasworks, the customers would have been left in darkness for an indefinite period.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTRIC BRAKE COUPLINGS.

SIR,—I should feel sorry if any expressions of mine were to obscure traction matters for anyone, and therefore regret not making my note clear enough for Mr. Bushell. It is quite evident now that Mr. Bushell wanted some information as to electric circuit couplers between railway carriages. The best method—such, indeed, as would occur to anyone when asked to devise an appliance of this kind—is so simple and effective that I thought it derogatory to anyone's knowledge to give details. If Mr. Bushell follows his advice to me, and goes to one of the railway termini—London Bridge, for instance (L.B. & S.C.R.)—he will see plenty of these couplings used for lighting the trains, and obviously they might serve also for electromagnetic brakes. I fear I cannot plead ignorance of the ordinary air-brake arrangements; in fact, some amount of experience has enabled me to differentiate a Westinghouse from a vacuum, and both from any others—but, of course, that is common knowledge.

Mr. Bushell will find my address in the electrical directories if he wishes to communicate with me at any time. I must refer him to the late officials for news of the electric traction company which he names.—Yours, etc.,

London, Feb. 13, 1895. FRANK B. LEA.

REVIEWS.

Central-Station Book-keeping: With Suggested Forms of Account. By HORATIO A. FOSTER, M.Am.Inst.E.E. New York: The W. J. Johnston Company, Limited. 1894.

It is perhaps typical of the great difference between the systematic solidity of English methods from the very outset and the decided want of system too often characteristic of progressive enterprise in the United States, that the author of this book should find it worth while not only to discuss the subject, but also draw up as guides a series of model account forms which his readers may adopt, wholly or in part, for the proper conduct of their business. The main thing in America is to *build* an electric railway or put up an electric lighting station: the best methods of working and most convenient system of book-keeping, etc., may be, it is thought, developed soon enough when the business is fairly set going. Hence there arises a demand—and a large one, too, apparently—for advice and information of the type contained in this book. In this country, however, we should say that it has but little scope except as a mere record of book-keeping systems abroad. So far as central-station work is concerned, the accounts of English companies are usually modelled alike, and fall in with Board of Trade requirements. Manufacturing and contracting companies, and other such private business enterprises, are of necessity carried on throughout with careful book-keeping methods, if the desire is real and evident to make them prosperous, not to say keep them out of the bankruptcy court. Mr. Foster's book is, however, well worth careful study by all those engaged in the management of electrical enterprises, for it contains a considerable number of excellent standards, as well as ideas and suggestions which may well be adopted even for the solid and substantial systems of accounting that are general in this country.

NEXT WEEK'S NEWS TO-DAY.

A Madrid telegram, received yesterday, states that the steamer "Dacia" has successfully joined the two ends of the cable from Cadiz to the Canary Islands.

Do not forget that a ladies night of the Electro-Harmonic Society will take place on Friday next, the 22nd inst., in the banquet-room of the St. James' Hall Restaurant, Regent-street, W. There is an excellent

Digitized by Google

programme, which has only reached us at the moment of going to press, and which will be given in our next issue.

Mr. Bryce, answering Mr. Wharton in the House of Commons yesterday, said that he hoped at the earliest opportunity to lay on the table the Bill he had promised for providing light railways. The sooner the better, Mr. Bryce.

In the House of Commons yesterday, Sir George Baden-Powell asked the Under Secretary of State for the Colonies whether he could give the House any further information as to the projected telegraphic cable across the Pacific Ocean. Mr. Buxton was understood to say that the negotiations were in progress, and it was not advisable at present to make any statement on the subject.

Another late comer is the announcement by the county of London and Brush Provincial Electric Lighting Company that Mr. Angus McLeod has resigned his position as managing director of the Scottish House-to-House Electricity Company, and that Mr. A. J. Lawson has been appointed by the directors as the engineer and manager. Mr. Teague remains resident engineer at Coatbridge. At the same time the registered offices of the Scottish Company have been removed to 49, Queen Victoria-street, E.C.

The half-yearly meeting of the National Telephone Company, Limited, was held yesterday afternoon at Cannon-street Hotel, when Mr. J. S. Forbes moved the adoption of the report, particulars of which have already appeared in our columns. He stated that it was necessary to provide a considerable addition to the reserve, in order to cover what might arise when the company's lease ended. Their capital was now £4,430,000, and it was important to bear in mind that their business involved the finding of ready money in anticipation of new subscribers. Every new subscriber cost about £40; and the additional capital of £134,959 was mostly spent in that way during the half year. They had nearly 600 exchanges scattered over Great Britain and Ireland. Lord Balfour of Burleigh seconded the adoption of the report, which was agreed to.

THE APPLICATION OF THE ELECTRIC ARC SYSTEM OF WELDING TO MACHINERY AND BOILER REPAIRS.*

BY HENRY FOSTER.

This subject was discussed on Tuesday evening by Mr. Henry Foster before the North-East Coast Institution of Engineers and Shipbuilders in a paper entitled "The Application of the Electric Arc to Machinery and Boiler Repairs," etc. The paper, of which the following is an abstract, was accompanied by numerous illustrations:

At the present time there are two principal systems of electric welding in successful operation, and each system possessing special features which render it more particularly adapted for certain classes of work than the other. Firstly, we have the Thomson-Houston system, in which the heating effect induced by the resistance to the passage of the electric current through the articles to be welded together, accompanied by a certain amount of pressure between the parts thus heated, is made to produce the required weld; and, secondly, we have the Benardos or arc system, in which the article to be operated upon is made to constitute one pole of the electric circuit, while a carbon pencil attached to a portable insulated holder, and held by the workman, constitutes the other pole, the electric arc—which is the heating agent of the process—being struck between the two poles thus formed. When steel or iron is being welded it is usual to make the carbon the negative pole, and the steel or iron the positive pole; but for other metals the poles are sometimes reversed. In welding lead, for instance, it is usual to work with the carbon positive.

In this paper the writer proposes to confine his remarks and illustrations exclusively to the Benardos or arc system of welding—which, having been considerably improved in detail during the last few years at the works of Messrs. Lloyd and Lloyd, Birmingham, at Newburn, and elsewhere, is now more generally known as "the improved Benardos system"—and more particularly to the application of this system to repairs of machinery, etc., done under his supervision. The method of working is a very simple one, and is practically identical in all cases. The only difference between the methods of working adopted by Messrs. Lloyd and Lloyd and those adopted at Newburn, is in the construction and arrangement of the resistances, and may be taken as generally illustrative of the methods adopted elsewhere, and shortly described as follows: At Messrs. Lloyd and Lloyd's Coombs Wood works, the welding plant is arranged as illustrated by Fig. 1. Here an ordinary lighting low-tension continuous-current dynamo is used, to the terminals of which a battery of Benardos accumulators is connected, and into which the current flows continuously. When the welding circuit is closed, the current flows from the dynamo and accumulators through a large regulating resistance, and by these means a discharge equal to about twice that of the capacity of the dynamo is available. In parallel with the terminals of the dynamo or battery as many

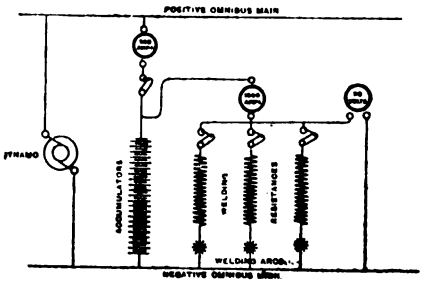

FIG. 1.

welders or welding machines as may be desired can be connected, and every welder is able independently to vary his current and pressure to suit the work in hand at the moment. One terminal of each welding system is connected by means of a flexible cable to a carbon pencil held in an insulated holder, which is in turn held by the workman, while the other terminal of the system is connected to the table on which the work lies or to the work itself. The special advantage of this arrangement of resistances and accumulators is that it admits of wide limits of variation of current and pressure to suit the different classes of work which may be in progress; and in the installation at Coombs Wood arrangements are made so that the works, offices, and foremen's houses are lighted, motors are driven, and the electric welding plant is supplied with current all from the same system of mains simultaneously.

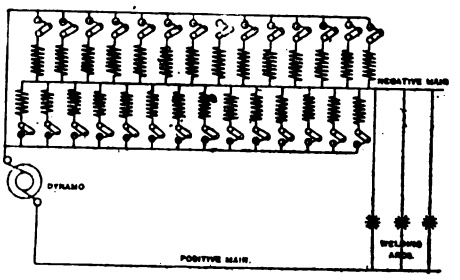

FIG. 2.

In cases where the current and pressure required for the work in progress are practically constant, and only welding is required to be done for the time being from the circuit, it is possible to work effectively without accumulators, providing large resistances are adopted, and this latter method of working, illustrated by Fig. 2, is that in use at Newburn. The efficiency of the method of working illustrated by Fig. 2 is not so high as that illustrated by Fig. 1, because during the time that welding is not being done the outer circuit is not closed, and no current is passing, consequently the whole plant is running light; but in a welding installation this defect may in a great measure be obviated by arranging two or sometimes three welders in the same circuit, and so arranging matters that when one man is welding the other one is dressing his work and making preparations for his turn. In any case, however, the method illustrated by Fig. 2 has the advantage of decreased first cost, and is more portable, and it becomes a matter of £ s. d. with each individual user as to whether the method of working as illustrated by Fig. 1, with its greater first cost and greater efficiency, or the method illustrated by Fig. 2, with its less first cost but proportionally less efficiency, is most suitable for the particular work to be done; bearing in mind that method No. 1 admits of a greater range of variation of current and greater length of arc being obtained than with method No. 2, and that with the lighter classes of work it is

* The shaded portion in the examples given in the illustrations indicates the nature and position of weld in each case.

Digitized by Google

essential to use as long an arc as possible, because the heating effect is more regular and better distributed. The real object of this paper, however, is not to discuss the relative merits of the different methods of arc welding under special circumstances, but to show by a series of illustrations (1) what has been done by the method of working illustrated by Fig. 2, and

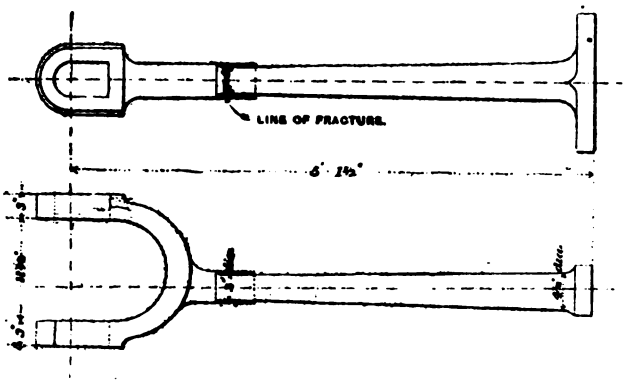

FIG. 3.

(2) to explain to those interested the simplest and cheapest method of doing similar work which the writer's experience would suggest.

GENERAL MACHINERY REPAIRS.

Fig. 3 represents one of the eccentric rods of the reversing engines which drive the plate mills at Newburn, and which was accidentally broken, as indicated, on August 13, 1891. The engines, which had only recently been erected, were being tested under steam (with a view to having all in readiness for the official inauguration ceremony in connection with the opening of the mills on August 15) when, owing partly to the sand and dust incidental to a new works, and partly owing to the negligence of the greaser, one of the eccentric straps seized, and the eccentric rod bent and broke close to double eye neck. The eccentric rod being of steel, and the position of fracture so awkwardly situated that it could not be readily welded in the ordinary way, it was decided to straighten the bent and broken rod and electrically weld it. This was done, and the engine with repaired eccentric rod attached was running again under steam at six o'clock the following morning. The eccentric rod as originally welded is still working, and has never since given the slightest trouble, although the engine in question has rolled every plate which up to the present has been made at Newburn.

Fig. 4 shows one of the steel roughing rolls for a bar mill, which under normal conditions works with heavy draughts on hard steel, and by which the wobbler end had been worn as indicated, until the coupling-box turned round without driving the roll, thus rendering the roll useless. The roll, which weighs over 50cwt., was taken out and the worn portions electrically welded up again to original size. The whole operation of taking out, welding, and putting in place again, only necessitated the mill standing for 24 hours. The welded roll has now been running for about six months, and although the wobbler is again wearing out, it is satisfactory to know that when it is again worn so that the coupling-box refuses to drive, the welding can be repeated again and again if necessary.

Fig. 5 shows one of a pair of cast-steel helical pinions, each weighing over six tons, for a large reversing plate mill. These pinions had to be taken out and the spare gear substituted owing to wobbler ends being worn, as indicated, by the constant reversing of the mill. With reversing mill pinions there is often a difficulty experienced in casting them of the exact hardness most suitable for the work. Either they are cast too hard, causing the pinion teeth to break before the wobbler ends are worn, or, as in this case, the wobbler ends are worn while the teeth are left perfect, owing to the steel being too soft. These wobbler ends were electrically welded up to the size originally made when new, and the pinions put to work again on January 28, 1895, and although since being welded they have not been working long, yet there is no need to anticipate trouble from the welding.

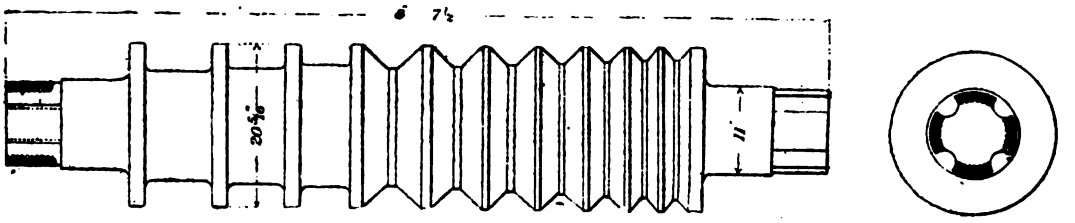

FIG. 4.

Fig. 6 shows the crankshaft of the small screwing engines fixed on the top of the plate-mill housings. The object of these engines is to turn the housing screws, and regulate the distance between the rolls, and thereby determine the amount of draught at each pass of the slab. The original eccentrics on these crankshafts were in halves and keyed to the shafts in the usual way; and so long as this arrangement existed, constant trouble was experienced, either due to the eccentric keys or bolts coming loose or to the eccentrics breaking. It was therefore decided

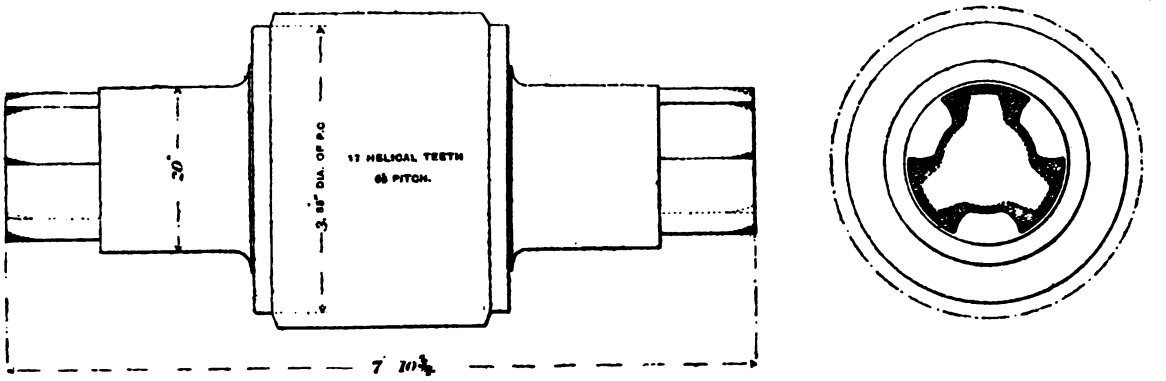

FIG. 5.

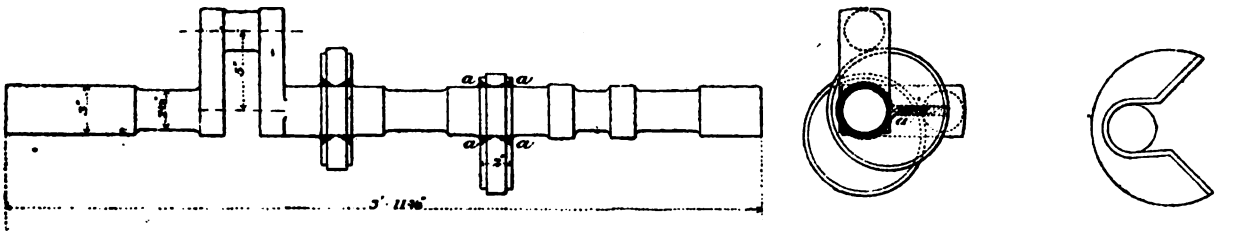

FIG. 6.

FIG. 7.

Digitized by Google

to electrically weld new steel eccentrics to the old crankshafts, and this was done as follows: Rough slabs of steel were smithed to the shape shown by Fig. 7. These slabs were then heated red hot, and clasped round the shafts, and the V-shaped recesses, *a a*, electrically welded up to form the complete eccentric in each case. The shafts were afterwards centred in a lathe, and the eccentrics turned to finished shape in the usual way adopted when turning eccentrics on a solid shaft. Two exactly similar crankshafts had eccentrics fitted in this manner, and neither of them has given the slightest trouble, although the first one has now been working for nearly 12 months.

(To be continued.)

PHYSICAL SOCIETY.

The annual general meeting was held on the 8th inst., the chair being taken by the retiring president Prof Rücker.

The **Treasurer** (Dr. Atkinson) presented his report for the year 1894. The balance-sheet showed a somewhat larger expenditure than in previous years, the increase being partly due to the new system of publishing abstracts, partly to the rent of rooms and the expenses of tea. The balance in the bank had increased by about £33 during the year, but the treasurer said that, strictly speaking, the society had trenched on its capital to the extent of about £30, and that this would probably be the last report for some time to come which would show a balance in favour of the society. The assets of the society exceeded its liabilities by £2,642. 0s. 5d.

Prof. Carey Foster asked whether it would not be possible in estimating the assets of the society to make some allowance for the stock in hand?

Dr. Atkinson replied that that had not hitherto been done, and the difficulty would be to assign a money value to the stock. The stock of the works of Joule and of other memoirs was, of course, decreasing, while the sale of the *Proceedings* was becoming somewhat greater. As regarded the securities of the society, their actual value would be about £200 or £300 more than appeared on the balance-sheet.

Prof. Rucker said that the society had deliberately entered upon a policy of expansion, and that they must be prepared to find the expenditure increasing. On the other hand, it was hoped that by making the society more attractive a greater number of persons would be induced to join. In view of the great advantages now enjoyed by members, there had been some suggestion of raising the subscription, but in any case he thought that they might look forward to the future with confidence.

The report was then moved and adopted.

The next business was the election of officers and council for the year 1895-6, and Messrs. Rhodes and Yule, being asked to act as scrutators, collected the balloting lists.

Prof. Carey Foster proposed a vote of thanks to the Lords of the Committee of the Council on Education for having allowed the society to meet at the Royal College of Science. At the commencement of the life of the society its founder and first president, Guthrie, had obtained permission for the meetings to take place at South Kensington, and the society had continued to meet there until their recent migration to the rooms of the Chemical Society.

The vote of thanks was duly seconded, and was carried unanimously.

Major-General Festing then proposed, and **Mr. Croft** seconded, a vote of thanks to the auditors, Messrs. Inwards and Trotter. This also was carried.

Mr. Trotter then proposed a vote of thanks to the retiring council; they had shown an energy which was rare in such societies, and had inaugurated an active and original policy, which must prove of the greatest benefit to the Physical Society and to physical science generally.—Carried unanimously.

Mr. Elder gave notice of a proposed alteration of the rules, the object being to allow the council under certain conditions to admit persons into the society without requiring from them the usual number of recommendations from members. It was pointed out that sometimes eligible persons, especially those resident abroad, were unable to enter the society because they were unknown to any of the existing members. The motion to sanction the proposed alteration was put from the chair and carried, but this decision will need to be confirmed at a subsequent meeting, of which due notice will be given.

Mr. Rhodes then read the following list of the officers and council elected for the year 1895-6: president, Captain Abney; vice-presidents who have filled the office of president, Dr. Gladstone, Profs. Carey Foster and Adams, Lord Kelvin, Profs. Clifton, Reinold, Ayrton, Fitzgerald, Rücker; vice-presidents, Mr. W. Baily, Major-General Festing, Prof Perry, Dr. Stoney; secretaries, Messrs. Blakesley and Elder; treasurer, Dr. Atkinson; demonstrator, Prof Boys; other members of council, Mr. Shelford Bidwell, Prof. Crookes, Messrs. Fletcher, Glazebrook, G. Griffith, Profs. Henrici and Minchin, Mr. Swinburne, Profs. S. P. Thompson and S. Young.

Prof. Rücker then vacated the chair in favour of Captain Abney, and the meeting was resolved into an ordinary meeting.

Mr. S. Skinner read a paper "**On the Tin Chromic Chloride Cell.**" He said that his attention had been attracted to the cell by an account published by Mr. Case, of New York. The cell had been stated to give no E.M.F. at ordinary room-temperatures, while it gave a considerable E.M.F. at 100deg. C. The author had found that when the cell was directly connected up to a galvanometer there was no current at ordinary temperatures and some current at 100deg. C., but when he had measured the E.M.F. by Poggendorff's method he had found ·44 volt at 15deg. C., and ·40 volt at 97deg. C. The cell, as originally described, consists of a tin plate and a platinum plate immersed side by side in a solution of chromic chloride; when the temperature of the cell is near to 100deg. C., and the poles are connected, the following reaction occurs:

$$Cr_2Cl_6 + Sn = 2CrCl_2 + SnCl_2;$$

and when the poles are disconnected and the cell cooled, the reverse change takes place. The author prefers to use as electro-positive metal an amalgam of tin and mercury instead of a tin plate, so that when the tin precipitated during cooling falls to the bottom of the solution, it is redissolved in the mercury, and the cell has regained its original state. When silver nitrate solution is added to chromic chloride, only two-thirds of the chlorine comes down as silver chloride, and this has led the author to suppose that the proper formula for chromic chloride is $2CrClCl_2$. Hence he works out the electrolytic action by means of a Grotthus chain.

Prof. Rucker asked whether a change of polarisation would explain the behaviour of the cell at different temperatures.

Prof. Carey Foster asked whether the reversed chemical action on cooling from a high temperature were accompanied by a reversed E.M.F.

Mr. Skinner said, no; the tin was precipitated throughout the solution, and not at the surface of the tin plate, so that no E.M.F. of the kind was to be expected.

Mr. Appleyard thought that Prof. Minchin had used tin chloride cells with two tin plates for electrodes, the cells only working when one plate was illuminated.

Mr. Skinner thought that heating acted by removing an obstacle.

THE CANNON STREET EXPLOSION.

BOARD OF TRADE REPORT.

In our last issue we summarised the causes assigned by Major P. Cardew for the recent explosions in Cannon-street on November 10. We now give Major Cardew's report, which bears the date of December 4, 1894:

This enquiry occupied three days, the 19th, 20th, and 23rd inst. Mr. W. Russell Griffiths appeared for the Aldermen and Commissioner of City Police, Mr. E. A. Baylis for the Commissioners of Sewers, and Mr. R. W. Wallace for the City of London Electric Lighting Company. These gentlemen rendered great assistance in elucidating all the facts material to the enquiry. I append my notes of the evidence taken and also a transcript from the notes of the shorthand writer employed by the City authorities. Twenty-nine witnesses were examined, of whom 17 were present at the time of the occurrence, several of these having suffered injury and electric shock. The other witnesses were various officials of the company and experts. Among these latter, Mr. Foulger, chief distributing engineer of the Gaslight and Coke Company, gave very valuable evidence. I have prepared a diagram showing the positions of the principal points referred to in this report.

Description of System.

It will be of advantage to shortly describe the system of supply in use by the City of London Electric Lighting Company, Limited. This consists of a high-pressure alternating-current supply by means of concentric mains to converting stations, which, as a rule, have been constructed underground, and from these a low-pressure supply is given to consumers by distributing mains. The supply has until lately been given from two generating stations—one at Wool Quay, near the Custom House, and the other at Bankside, on the south side of the river. These stations were only intended to provide temporarily for the lighting, and a large permanent station has recently been constructed at Bankside and partly equipped with plant and machinery. The operations connected with the transfer of the load to the permanent station were being carried out at the time the accident occurred.

General Account of Occurrences.

It appears that on the 10th ult. about 1 p.m., a mare attached to a brougham belonging to Mr. C. Boutland, of 21 Cousin-lane, Thames-street, E C, was turning out of Cannon-street into Budge-row, when she pitched forward on her knees, then turned on her side and died in about four minutes. The driver, G. Clark, got down and immediately felt an electric shock in both legs. He was unable, on account of the intensity of the shock, to touch the mare, but disconnected the traces and backed the brougham clear. A warehouseman, named James Hutchins, who was at work in Budge-row, went to assist, but he also experienced a severe shock, and was unable to approach the mare closely. Shortly afterwards the iron lid of the street box opposite the Liberator Building Society's office was lifted about 2ft. in the air by an explosion, and thick smoke issued from the box. According to one witness there were three reports, each accompanied by a flash of blue flame. This street box is the one marked B. Two witnesses received severe shocks by stepping on to the street box cover on the opposite side of Budge-row. Apparently simultaneously with the explosion in Budge-row a more serious explosion occurred at the street box at the corner between Walbrook and Cannon-street, west side. In this case the lid was blown sufficiently high to be shattered by its fall, and the paving-stones in the vicinity were also dislodged. Several persons were injured by

Digitized by Google

this explosion; in most cases the injuries received were only trifling. Two persons, however, I was informed, were unable to attend my enquiry on account of the injuries they had received. The veterinary surgeon who made a *post-mortem* examination of the mare stated that all her organs were perfectly healthy, and he could not account for her sudden death otherwise than as a result of severe electric shock.

The immediate causes of these serious accidents were—the breaking down of the insulation of a high-pressure main in the street box at the corner of Budge-row leading to the formation of a powerful electric arc between the outer conductor of this main and the end of the iron pipe, forming a conduit for the mains under Budge-row, which projected into this street box, and the consequent charging of this pipe to a dangerous extent; and the presence of gas in the electric light company's pipes and street boxes to an amount which formed a highly explosive mixture in the street box at Walbrook where the more serious explosion occurred, the gas being fired by the electric arc. It is true that Mr. Foulger, on behalf of the gas company, informed me that since the accident they had tested the soil in the vicinity of this street box, and had not detected the presence of gas in it, but, on the other hand, expert evidence was given of the actual presence of a highly explosive mixture of gas and air in a neighbouring street box, connected with it by means of several pipes, on the 19th inst. No gas was detected in the box where the explosion occurred at this test, but the cover of an intermediate box was loose at the time, thus providing a means of escape for the gas. On the whole, considering the nature of the explosions, the fact that one of them occurred at a distance of 26 yards from the electric fault, that the locality was admitted to be one where defects in gas-pipes had been rather frequent in consequence of the disturbance of the subsoil by the excavation for the completion of the Inner Circle Railway, and that no system of ventilation had been provided by the electric light company for their conduits, there can, I think, be no doubt that the explosions were due to the firing of an accumulation of gas in the conduits by the electric arc formed at the point where the main broke down.

The breakdown of the main was the consequence of a careless mistake, whereby an abnormal electrical pressure was brought upon the outer conductor, and this pressure found a point of weak resistance, probably a partial abrasion of the insulation, where the main was bent to enter the pipe leading from the box. The existence of mechanical injury to the insulation is almost a necessary postulate, since a piece of main containing the fault, now in my possession, shows the insulation to have been of ample thickness and first-class quality, and it should easily have withstood the maximum pressure to which it was on this occasion subjected. Indeed, I am informed that it had been tested with a much greater pressure.

The mistake that was made was as follows: Two new mains had recently been laid—one from the generating station at Bankside to Watling-street converting station, the other from Bankside to Milk-street converting station. It was intended to connect the Watling-street main into the new switching apparatus provided for it at Bankside, but the end of the Milk-street main was put in by mistake, while the end of the Watling-street main was left lying on the outer lead coating of another new cable. The end of this main was prepared to be put into its switch pillar and was not sealed up, as otherwise it should have been, and the inner conductor must have been very nearly in contact with the lead coating, and thus by means of the iron rack in which the cables were lying with the lead coatings of several other cables, all of which coatings were thoroughly connected to earth. While the Watling-street main was lying in this position instructions were sent to the foreman of the transformer department, Mr. Joseph McMahon, to switch the pressure on to it from the Watling-street converting station. As soon as he did this an electric arc started at Bankside between the end of the inner conductor of this main lying as above described and the lead coating adjacent to it, thus effecting a connection of the inner conductor of this main, and of the whole system of mains, to earth.

Now, in a concentric system of mains used for the transmission of alternating currents, under normal conditions the outer conductors are very nearly at the potential of the earth, and practically the whole working pressure exists between the inner conductors and earth. But a connection to earth of the inner conductors tends to reverse this condition, and raises the pressure between the outer conductors and earth. The inner conductor of the Watling-street main may have been absolutely touching the lead coating or "dead to earth" when first charged, and in this case the pressure between outer conductors and earth would have been raised to the full 2,000 volts at which the station was working. When the arc started in the street box in Budge-row, however, the pressure would be probably nearly equal on the inner conductors arcing to earth at Bankside and the outer conductors arcing to earth in Budge-row. The breakdown occurred in full daylight, so that the load on the station was comparatively light, and the sudden increase of current was at once noticed at Bankside, both by the powerful disturbance it caused in the telephone at which the engineer in charge of the station happened to be at the time, and by the peculiar noise, indicative of a short-circuit, made by the generating machines.

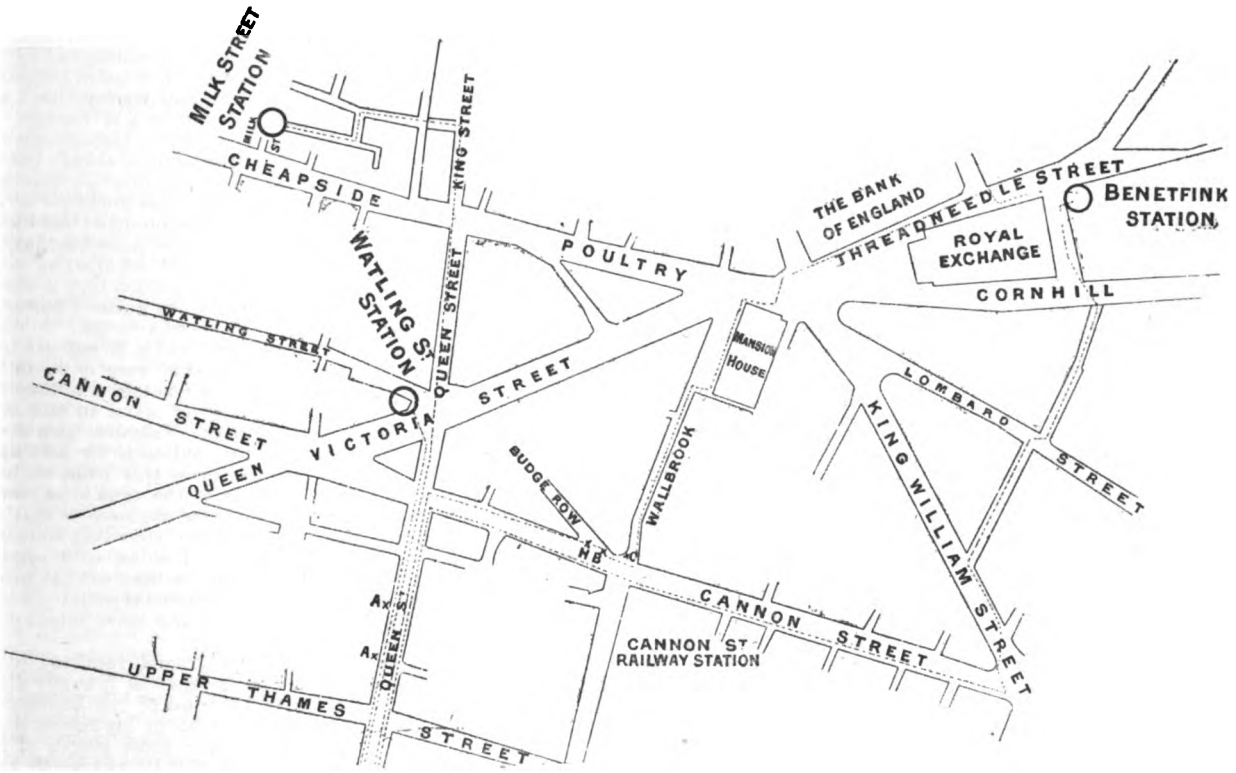

Diagram showing the principal points referred to in this report. Ax Ax are points between which the Watling-street and Milk-street mains were crossed. Bx shows the box where the earthing took place. C is the box where the explosion occurred, and Hx is the place where the horse fell.

Some of these generating machines were at once switched out of circuit, and the abnormal load thrown upon the only two machines left running caused such a lowering of pressure on the whole system that the lights are said to have gone out altogether. The foreman at Watling-street station noticed a flickering of the lights shortly after he switched the new main on, and suspecting that his action had in some manner occasioned a fault he at once switched it out of circuit. This was certainly the best thing he could have done, but it did not remove the fault, since the electric arc in the Budge-row street box had, of course, rapidly burnt away the insulation between the two conductors of the main and established an arc, or short-circuit, which still continued to burn furiously, melting away a considerable amount of both conductors. The engineers at Bankside in the meantime after consultation determined to switch off mains in succession until the fault was discovered, and by this means this fault was removed from the circuit.

Explanation and Comment.

Having thus given an outline of the occurrences, I will now deal more particularly with the points in which I consider the company and their officers and employés were to blame for want of judgment, carelessness, and inattention to the regulations

Digitized by Google

imposed by the Board of Trade, and with the manner and means by which any repetition of such an alarming and serious accident may be avoided.

1. In the first place, it will naturally be asked, how was such an egregious mistake committed as the charging of one main under the impression that it was another? Bearing in mind that the pressure was one dangerous to life, it is evident that the consequences of such a mistake might easily have been fatal, since the end of the main that was charged might have been in a man's hand at the time.

2. Why, when the breakdown had occurred, since it certainly occasioned an excessive current in the mains affected, were these mains not automatically cut out of circuit?

3. Why, in the absence of proper automatic disconnectors, were there not at any rate some indicators to show the disturbance of potentials with regard to the earth and the rush of current through the mains affected; and how far might such indicators have prevented the breakdown or shortened the duration of the dangerous condition?

4. How was it that the surface of the street at Budge-row could become so dangerously charged in consequence of any defect in the electric mains; and how can this danger be removed?

5. Why was not the high-pressure main in the street box enclosed in strong metal casing efficiently connected to earth as required by regulation 7, *vide* Appendix II., since this box also contained low-pressure conductors?

6. Why was the accumulation of gas allowed to which the company attributed the explosion, and which they have themselves proved to exist in a neighbouring street box since the explosion?

1. The facts elicited at the enquiry with regard to this point disclose, in my opinion, great negligence on the part of some of those concerned. It appears that the two new mains to the Milk-street and Watling-street converting stations respectively run side by side down Queen street. The pipes to contain these mains had been laid some time previously, but the mains themselves were drawn in between October 9 and November 7, some delay having occurred during the progress of the work owing to the cables not being ready, and to alterations in one of the street boxes. The mains are drawn into the pipes in lengths extending from one junction-box to the next, the ends of each length are labelled to correspond, and the jointers subsequently effect the necessary joints at the junction-boxes. Owing probably to some obstruction met with, the pipes between two junction-boxes in Queen-street were to some extent twisted round each other so that their ends occupied different relative positions at the two boxes. The two mains were drawn in at the same time according to Mr. A Cook, the superintendent of cable-laying, and probably in consequence of the twisting of the pipes either the labels were wrongly applied on the ends of the cables at one side of one or the other of these junction boxes, or the jointers jointed ends marked "Watling-street" and "Milk-street" together.

There is a direct conflict of evidence on this point between the foreman in charge of the laying and jointing respectively, but I do not think it is necessary that the Board of Trade should enquire too minutely into the question of the exact proportion of blame to be borne by the various subordinate officials of the company. The main fact is admitted that between this point and Bankside station and in the station itself the main to Watling-street was labelled Milk-street, and *vice versâ*. It is not, however, so surprising that such a mistake should have occurred, considering that the mains were laid and jointed up at the same time, and that the engineer in charge had not apparently given very close personal supervision to the work, as that one of these mains should have been charged to high pressure and connected into an electrical circuit, the E M.F. in which was maintained by large engines and dynamos amounting to over 1,500 h.p., without previously identifying the main—that is to say, ascertaining by the very simplest electrical test—a test thoroughly understood by every telegraph linesman's assistant—that one of the cables brought into Bankside was in connection with the cable in Watling-street station, and which of the two it was.

This blunder appears to have been partly due to a misunderstanding between the superintendent of cable-laying and the electrician in charge of testing, but principally, I think, to the latter having made a report that the Watling-street cable was good without having ascertained that the rough test of insulation, which was the only test he had taken, had been really applied to the whole cable. Had he taken the precaution to test this by directing the distant ends of the main to be connected together so as to pass a current through the circuit thus formed, the wrong labelling of the two mains would have been at once discovered. It also appears to me that in a matter of so much importance the superintendent of cable-laying was too easily satisfied that the main was correct when he knew that only a rough test had been made, and that he might with advantage have been present when the main was switched on.

2. The answer to this is that the fuses inserted with the object of providing an automatic means of cutting any main out of circuit in the event of a breakdown required much too large a fusing current to be an effective protection, more especially since under the system of cross-connection of converting stations at present in use, the fault will draw current from each end of the main so that only a proportion of the current which is doing the mischief passes through either fuse. In this instance the main which broke down in Budge-row was protected at each end by fuses calculated to act with 700 amperes passing, and it was practically impossible for the generating power running at the time to actuate them. The reason alleged for the use of such large fuses is that up to the present time the whole supply has been given through a few mains, and any failure in one of these mains would throw an excessive load on the others. Fuses calculated on the normal maximum load for each main would therefore be insufficient to carry the increased working current in such a case, and a total stoppage of supply might result. Since, however, the maximum current intended to be carried by any one main is only 150 amperes I consider that the fuses used were far too large, even from the point of view that continuity of supply was the first consideration. The proper proportioning of fuses does not appear to me to have received due attention. The guiding principle seems to have been to take care that they were so large as not to cause inconvenience by acting.

It is at times of light load that large fuses fail to act, and I am of opinion that it would be a desirable precaution on all large mains used for high-pressure supply to use a small fuse for light loads and switch in a larger one before the time of heavy load. Of course, a reasonable margin must be allowed for possible unforeseen demands for current, and inattention might cause some trouble, unless the switching-in of the large fuse could be provided by automatic means, but the small fuse might be arranged to give warning when the current began to exceed its capacity. While on the subject of fuses I would direct attention to the omission on the charging of the new Watling street main of a very simple precaution, which had it been taken would certainly have prevented the accident—viz, to charge the new main in the first instance through a fine fuse wire. Had this been done the moment the arc started at the other end of this cable, the pressure would have been cut off

3. The observation of the potentials, with regard to the earth, of the two sides of an electric supply circuit is rarely provided for by electric light engineers, although it is a very important precaution, more especially in the case of high-pressure systems. Where the mains consist of separately insulated conductors, the occurrence of any fault of insulation is at once detected by the effect produced on their potentials, and the insulation resistance of the whole circuit can be obtained at any time without any stoppage of supply being necessary for purposes of testing. In the present case, where the mains are concentric throughout, and where the potential of the outer conductor should always remain nearly the same as the earth, any rise of potential on this conductor must indicate a fault and a dangerous condition of the circuits. Such a rise of potential must have occurred before the breakdown in Budge-row took place, and it is probable that if a simple indicator of such rise had been fixed at Watling street station and if the foreman there had been warned that it was an indication of danger, to be observed when any unusual operation was in progress, the accident would have been avoided.

Then, again, as regards the current indicators, it appears from the evidence that the engineers at Bankside were quite in the dark as to where the unusual current was passing, and they had to resort to the expedient of switching off mains in succession until they discovered which were affected. Valuable time would have been saved had there been a current indicator for each main to refer to. I do not however, wish to press this point too hard as the new switch-room at Bankside was at the time in an incomplete state. The evidence of the station engineer is that the faulty cable was cut out in 13 minutes; the recording voltmeter curves show a duration of 15 minutes. I think with suitable indicators and prompt action it might have been cut-out within one minute and had this been done the explosions would not have occurred, and possibly even the death of the horse might have been avoided.

4. The charging of the surface of the ground resulting in the death of a horse and shocks to human beings was brought about in identically the same way as in the case of the accident at Bournemouth on January 8 last, referred to in my report dated January 20, 1894. Here, again, there was a short length of iron pipe (about 37ft. in this case, 32ft in the Bournemouth case) terminating at the brick walls of the junction-boxes at each end, and not in metallic connection with the iron pipes on the other sides of these boxes. The depth of the pipe below the street level varied from 1ft. 4½in. to 2ft. 6in (about 18in. in the Bournemouth case). In this case it is true that the surface of the street was wood pavement, which might be supposed to offer considerable resistance to the passage of an electric current, but the weather had been unusually wet for some time before the occurrence, and the wood blocks and underlying concrete were no doubt thoroughly saturated with water and their resistance thereby diminished.

Since the Bournemouth accident I have carried out, with the assistance of the instructor in electricity at the School of Military Engineering, Chatham, some experiments to determine the rate of fall of potential on the surface of the ground produced by charging a pipe under similar conditions. The results of these experiments are detailed in a joint paper communicated to the Royal Society, and published in their *Proceedings*, a copy of which I attach to this report (*vide* Appendix I). They fully confirm the view I took of the nature of the Bournemouth accident which has been repeated in this case. The cause of the fatal shock to the horse and of the comparative immunity of human beings is fully stated in the report and paper above referred to. To remove this particular danger, the whole system of iron pipes enclosing high-pressure mains must be thoroughly connected together, and additional precautions, which are detailed below, should be taken to prevent any possibility of a discharge from mains to pipes. The duty of providing against this danger is distinctly imposed upon the company by Regulation 8 (*vide* Appendix II.), and they should not have permitted short lengths of pipes containing high-pressure mains to remain isolated.

5. I consider that there was a distinct failure to comply with Regulation 7, and I had previously brought this matter to the notice of the company. It had also been brought to their notice

Digitized by Google

by the engineer to the City authorities. It happened that in this case the low-pressure conductors did not become dangerously charged, and they do not even appear to have been damaged either by the electric arc or the explosion, but the strong metal casing would probably have protected the cable against injury to the insulation, and even in the event of a breakdown would have much reduced the chance of accident by making a metallic connection from pipe to pipe across the street box. If an arc had been formed at all under these conditions it would have been a much smaller one, and time would have been given to cut off the pressure before the arc had eaten its way through the metal of the casing, or for the fuses to act, had they been sufficiently sensitive. The company now propose to encase the high-pressure mains across all street boxes by wrapping them with several layers of stout copper strip continued into the pipes at each side, and this precaution alone will, in my opinion, considerably reduce the risk of similar accidents.

6. The question of the accumulation of gas in the conduits and street boxes of the electric lighting company is the most difficult to deal with of all the questions raised by this accident. The danger is a well-recognised one and Regulations 14 and 15 (*vide* Appendix II.), impose upon the company the duty of efficiently protecting their conduits and street boxes against such accumulation. That this duty had not been adequately performed had been forcibly demonstrated by several previous explosions, of which particulars are given in the reports marked (*a*). One of these, the double explosion on January 8 last, was investigated by me, and the Board of Trade called the attention of the company to the fact that they were not adequately complying with Regulation 15. The company thereupon informed the Board of Trade that they were maturing a scheme of ventilation for their conduits. At this enquiry, however, it appeared that no means of ventilation had as yet been provided. What has been done is to keep two men constantly employed inspecting street boxes and reporting any accumulation of gas. These reports have been forwarded to the Gaslight and Coke Company, and in many cases the information thus supplied has enabled leakage of gas to be detected. Since the accident the number of men employed in opening street boxes has been increased to 12.

It certainly appears that up to the time of the occurrence of the recent accident the company had not displayed sufficient vigour in dealing with this very important matter, but it must be admitted as some excuse that there is at present some diversity of opinion as to how, in cases where the soil is heavily charged with gas by leakage from the gas-pipes, it can be best prevented from accumulating in the conduits of the electric lighting companies.

Thus, at the present enquiry, Mr. D. Cook, on behalf of the electric lighting company, gave particulars of a scheme of thorough ventilation which they were prepared to adopt, while Mr. Foulger, who appeared on behalf of the Gaslight and Coke Company, stated that in his opinion this system of ventilation would be dangerous, and General Webber gave it as his view that the pipes and conduits should be plugged at each street box to prevent percolation of gas, thus making thorough ventilation impossible. The company have a very extensive network of pipes occupied with their own mains, and they have also numerous spare pipes laid in communication with the same street boxes, and intended, I understand, to accommodate telephone wires. The whole length of their pipes and conduits exceeds, I am informed, 700 miles.

In my opinion, a system of thorough ventilation of all street boxes by natural or forced draught should be provided, and, in addition, everything possible should be done to prevent the entry of the gas by making the sides and bottoms impervious. Also the air capacity of these boxes should be reduced where practicable by filling them with incombustible material. At the same time the system of regular inspection should be continued, and immediate notice of any leakage of gas detected given to the gas company, who appear to take a very reasonable attitude in the matter, and expressed through Mr. Foulger their desire to render all the assistance possible towards the prevention of any further explosions. In the provision of ventilating pipes, it will be necessary to consider the possibility of the ignition of the gas issuing from these pipes. If they are attached to houses they should in all cases be carried up above all windows, and if they are erected in the streets the orifice should be at least 8ft. from the ground.

So far I have dealt with the immediate causes of the accidents and the mistakes made, but it is, I think, desirable also to draw attention to the fact that the work of the officials of this company has been lately carried out under very difficult conditions. The company commenced business with two so-called "pioneer" stations, and have erected and partially equipped the new generating station at Bankside, in order to be able to efficiently meet the rapidly-increasing demand for electric light. In this station nearly the whole of the plant and equipment is of novel design and unusual size and power, and the difficulties met with in the thorough testing and adjustment of this must naturally have been considerable. Before, however, the station was completed, before much of the plant had even been erected, still more before it could possibly have been thoroughly tested, and the adaptation of each part for its required action sufficiently studied by those who were to use it, the work of supplying electric energy to the City of London was thrown upon the new station.

The whole of the operations connected with the transfer of the load had to be carried out without interfering with the continuity of the supply, and at the same time the system of distribution mains was largely added to and remodelled. It is certain that in this transition stage risks were run—risk to the apparatus, risk to the employés of the company, and, as has been practically demonstrated, risk to the public. Here, I think, we have the real element of danger, which may, if not properly guarded against, occasion even more serious accidents. The same unfortunate experience has been the fate of other electric lighting companies. More especially are companies using a high-pressure system liable to become involved in the difficulties of a transition stage, since they are able to start with a very small capital expenditure, and yet carry the supply over a large district, picking up a customer here and there, while with low pressure this is impossible.

Requirements.

I will now summarise the precautions which should be taken by the company to prevent a recurrence of the accidents which form the subject of this enquiry.

1. In the first place, greater care is necessary in the testing and identification of new cables before connecting them to the high-pressure system.

2. Every new cable should be connected to the charged system in the first instance through a fine wire fuse, to be kept in circuit for at least two hours before any working current is passed through the cable.

3. Prompt action of the safety fuses should be secured by properly proportioning them to the working currents, and, if found practicable, by the use of more sensitive fuses at times of light load.

4. The interconnecting mains between converting stations should be kept out of circuit, except where in any case they may be absolutely necessary to maintain the supply, so that in the event of a breakdown of a main, current shall not be supplied to the fault from both ends, thus rendering the action of the safety fuses uncertain.

5. Suitable indicators should be provided at the generating and converting stations of the current passing in each main and branch connection, and especially of the pressure between the outer conductors and the earth, unless the company prefer to provide against the possibility of this pressure becoming large under any conditions by making an efficient connection of all the outer conductors to earth at the generating station. Of course, this can only be done with the approval of the Board of Trade with the concurrence of the Postmaster-General. This approval has been already obtained by the London Electric Supply Corporation and several other companies using concentric cables. Such an earth connection seems so far to have had no ill results, and it is certainly of great value in the interests of the public safety.

6. All high-pressure mains, where they pass through street boxes, should be enclosed in strong metal casing extending to some distance into the pipes at each side, so that the whole length of main shall be enclosed within metal which is in connection with earth throughout its length.

7. Accumulation of gas should be prevented by thorough ventilation, by making the sides and bottoms of street boxes impervious to gas, and by filling up the boxes as far as practicable with incombustible material.

8. Finally, while the company's arrangements for generation and distribution are still in a transitional stage, and while new and untried apparatus has to be brought into use, the very greatest care and the closest possible supervision are necessary. There is, I think, reason to hope that the company have now nearly completed the task of getting their system into proper working order, and if the precautions I have specified above are thoroughly carried out, I do not consider that there will be any further cause for anxiety as regards the public safety.

(To be continued.)

COMPANIES' MEETINGS.

HOUSE-TO-HOUSE ELECTRIC LIGHT SUPPLY COMPANY, LIMITED.

The ordinary general meeting of the above Company was held on Friday last at their offices, Richmond-road, Brompton, Mr. H. R. Beeton, the chairman of the Company, presiding.

The **Chairman**, in moving the adoption of the report and accounts, printed in our last issue, said that the business of the Company continued to show a steady growth, and the number of lamps connected during the past year was greater than during the preceding three years. The increase in the gross revenue was £1,452, and this had been earned at a reduced expenditure of over £400. The reduction in expenses was general throughout the revenue account, and testified to the more effective general supervision. The capital account showed an expenditure of £6,670, as compared with £7,409 during the previous year. Of this nearly £3,000 had been expended on new mains. This was, for the time being, a more or less unproductive expenditure. In view of the results now presented to the shareholders, the directors had under their consideration, in the general interests of the undertaking, the question of making a substantial reduction in the price of current to consumers. The Board were not yet in a position to make a definite statement in this respect, but they hoped that when the change was made it would not affect the net revenue, though it would affect the rate of progress of the Company. Since the issue of the report, the directors had not received the accounts which they had expected from the Leeds and London Company. The directors were disappointed that the business transacted under the agreement with that company had not been productive of profit, and they would investigate the causes. The Board felt that the satisfactory results which they were enabled to present to the shareholders

Digitized by Google

were in large measure due to the services of Mr. William Page, the managing director, and Mr. Bowden.

The motion was seconded by **Mr. W. F. Leese** and supported by **Mr. W. Page**, and carried.

Mr. Beeton moved, and **Mr. Page** seconded, a motion that 7 per cent. be paid on the preference shares, and this was agreed to.

Messrs. Beeton and Page were re elected as directors, and Messrs. Theobald Bros. as auditors.

WATERLOO AND CITY RAILWAY COMPANY.

The second half-yearly general meeting of the shareholders of this Company was held last week at Waterloo Station, Mr. W. S. Portal occupying the chair.

The **Chairman** said that there was an expenditure of £6,163 up to June, 1894, and £5,269 during the last half-year, making together £11,432. There would be no further call during the current half-year, but there might be one in the subsequent half-year. A report up to date from the engineers mentioned that the contractors commenced operations by constructing a large timber stage in the River Thames, above Blackfriars Bridge, in which they had erected all their engines and machinery for the construction of the tunnels, including air-compressing machinery for driving through water-bearing strata, electrical plant for lighting the tunnel and running the excavations to the shafts. From this stage two large circular shafts, 16ft. in diameter, were sunk in the line of each of the tunnels, and the driving of the up tunnel in each direction was commenced on November 28. The material through which the tunnel was being constructed was the solid clay, entirely free from water, and in the Waterloo direction it had cleared the river, and was now underneath the wharf on the south bank. Towards the City the tunnel was also making rapid progress, and was approaching the northern bank of the Thames. Altogether 670ft. had been driven and lined with cast iron. The work was carried on without cessation day and night, except between six o'clock on Saturday evening and midnight on Sunday, and, so far, everything had gone on satisfactorily.

After some discussion the report was adopted.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY, LIMITED.

The ordinary general meeting of this Company was held at Cannon-street Hotel yesterday morning, Mr. S. W. Silver occupying the chair.

The **Chairman**, in moving the adoption of the report and accounts, which were published in our issue of last week, and the declaration of a dividend of 5 per cent. for the half-year, could not help saying that the directors were disappointed at the results after the hard struggles the Company had gone through, but they had suffered from the general depression in trade. Competition had increased and over-production had decreased profits. Also the condition of the money market and the low rate of interest caused people to be seeking investments in manufacturing business. Their cable steamers had been at a standstill. On the other hand, they had been able to buy material cheap. There were signs of a revival, but great caution was necessary, for a new system of doing business was coming into vogue which suggested losses as much as profits. Rates and taxes had been on the increase. The Company had tendered to the Canadian Government for the laying of 8,000 miles of cable from British Columbia across the Pacific to Australia, and they had reason to believe that their offer was receiving consideration. The directors were indebted to the Hon. Henry Marsham, one of the directors, who had offered to accompany Mr. Hamilton Gray in connection with this matter. The works at Silvertown and in France were highly efficient, and fairly well occupied. If the cable contract could be obtained and their steamers utilised, he hoped there would be a more favourable account of their labours in July next.

Mr. Robert Henderson seconded the motion.

The **Chairman**, in reply to questions, said that the reserve fund was invested in the business, that the stock bought below value was being used at the market price of the day, and that the result of the Pacific cable would be publicly announced.

The motion having been unanimously adopted, **Mr. Silver** moved, and **Mr. R. Henderson** seconded, the re-election of the Hon. Henry Marsham and Mr. A. Weston Jarvis as directors, which was agreed to. Mr. J. F. Clarke was reappointed auditor.

Mr. Matthew Gray, managing director, said he had visited the works in France four or five weeks ago. He found the whole place busy and the machinery in first-class order. There was no bother about strikes, and the men were doing their work very satisfactorily. The works were in better condition than they had ever been, and the work was being turned out well and at as cheap a rate as any works in France.

LIVERPOOL OVERHEAD RAILWAY COMPANY.

The thirteenth half-yearly general meeting was held in Liverpool on Monday, Sir W. B. Forwood presiding.

The **Chairman**, in moving the adoption of the report and accounts (which were published in our issue of the 1st inst.), said that he believed the report would be satisfactory to the shareholders. From the report they would see that the gross revenue of the railway for the half-year ending December 31 was £25,700, and the profit, after deducting working expenses, amounted to £8,538. Out of this they had paid interest on their debentures £2,521, which left them £6,017, to which they had added the balance brought forward from the last half-year, £1,242, which made the sum available to be dealt with by them £7,256. They recommended the payment of a preference dividend of 5 per cent.—£2,428; also a dividend at the rate of 2 per cent. per annum on their ordinary shares, amounting to £3,750. This would leave a balance to carry forward to the next half-year of £1,087. In the half-year they had opened the north extension to Seaforth, and had also opened three new stations—one at Seaforth, one at the Langton Dock, and another at the Nelson Dock. Whilst they had derived increased earnings from that extension, there had necessarily been an increased expenditure. The train mileage run during the half-year was 314,472 miles, as compared with the same half of the previous year 243,539 miles, being an increase of 71,933 miles. They carried 3,641,397 passengers, as against 2,475,629, showing an increase of 1,166,000 passengers. When they originally issued the prospectus the directors were bold enough to say that they expected the traffic upon the line would be six million passengers per annum, but many people thought that in forming that estimate they were very sanguine. They were now glad to be able to report that the traffic had reached quite seven million passengers per annum. Nor did he think they had by any means reached the maximum of their traffic, because the more facilities they gave for travel the greater the traffic would be. Coming to their gross revenue, it was £25,675 as against £18,343 in the corresponding half of the previous year, showing an increase of £7,333. Their average receipts per passenger amounted to 1·61d., but he was glad to tell them that the last two months, since they made some readjustments in reference to return fares, their average receipts per passenger amounted to 1 91d. On the other side, their expenditure had been £17,162—that was to say, their working expenses—as against £13,732, an increase of £3,430. They had put an additional sum of £400 to the account of the cost of maintenance of ways and works. They thought this provision for the maintenance of the permanent way was very wise. The cost of the maintenance of their stations had also increased. The directors, he thought, were justified in taking the working of the line upon their own shoulders and terminating the contract with the Electric Construction Company. Comparing the expenses of their line with those of the City and South London line, he got the following figures. The working expense of the overhead railway per train mile was 13·10d., whereas on the City and South London line it was 15·36d. However, he thought it ought in fairness to be stated that with regard to the City and South London Company their stations were approached by lifts, and no doubt the working of the lifts added to the cost of working the line. Their locomotive expenses amounted to 3¼d. per train mile, as against 6·3d. on the City and South London line. The Liverpool Company had the advantage of a more economical system of motors than the City and South London Company, but he believed the latter company were about to adopt it. Taking the whole of their working expenses, they came to 66·84 per cent., but they hoped to see their way to make a considerable reduction and bring it down to 60 per cent. Although they had been running throughout the entire time trains every five minutes, 96 per cent. of their trains had been on time. The result was their line had become very popular. With regard to the southern extension, the directors thought that the time had arrived for it. The new line would be five-eighths of a mile in length. Starting about 200 yards on the north side of the Herculaneum Station, it would cross on iron girders to the foot of the Cheshire Lines goods yard, then proceed through a tunnel, emerging at the foot of Park-road, near the ancient chapel of Toxteth. They proposed to have a new station at the Dingle, which would be within a few hundred yards of Prince's Park, and a mile off Sefton Park. The engineers estimated that the cost of construction would be £87,000, and the cost of land, easements, and engineering expenses £10,000, showing a total of nearly £100,000. They hoped to be able to convey passengers from the Dingle to the pierhead in 12 minutes, thus beating all existing means. They had no intention of asking any further extension. With this addition the line would be complete, and it would not only facilitate the dock traffic, but would put them in communication with good feeders at both ends. As to how they would provide the necessary capital, it had occurred to the directors that by offering ordinary and preference shares in certain proportions they would make the issue attractive, and they believed that the shareholders would have sufficient faith in the undertaking to provide the capital without their having to go outside.

Mr. Richard Hobson seconded the motion, which, after some discussion, was carried.

A special meeting subsequently held approved of the construction of the southern extension railway, and authorised the directors to issue 7,500 ordinary shares of £10 each (being the unissued portion of the Company's original capital of 45,000 ordinary shares of £10 each).

LIVERPOOL ELECTRIC SUPPLY COMPANY, LIMITED.

Directors: Arthur Hill Holme (chairman), J. S. Harmood Banner, Samuel H. Holme, Sir David Radcliffe, Th. A. von Sobbe, J. C. Vaudrey, D. de Ybarrondo. Managing engineer: A. Bromley Holmes, M.I.C.E.

Report of the directors submitted to the shareholders at the ordinary general meeting of the Company held in Liverpool on Friday last.

The directors beg to submit herewith their twelfth annual statement of accounts, and are again able to report a steady increase in the demand for electric light. The total number of lamps connected to the Company's supply mains on January 1, 1894, was 25,784, and on December 31 31,792. The amount to the credit of profit and loss account, including the balance

Digitized by Google

brought forward from last year, is £15,601. 7s. 4d. Out of this sum an interim dividend at the rate of 5 per cent. per annum was paid for the half-year ending June 30, and the directors recommend the payment of a dividend at the rate of 6 per cent. per annum, free of income tax, for the half-year ending December 31, 1894. They also recommend that the sum of £1,359. 5s. be added to the reserve fund, carrying forward the balance of £1,136. 8s. 10d. to next year's account. The expenditure on capital account during the year, including a proportionate charge for general expenses, has been £40,786. Considerable additions have been made to the plant at the Highfield-street and Oldham-place stations, and the mains have been extended where necessary to meet the demand. Applications for the light from the residential districts served from the Company's Lark-lane station have come in slowly, owing no doubt to the depressed state of trade, but the directors anticipate that in the future this district will form a very valuable section of the Company's supply area, without requiring any large capital expenditure. The shareholders are aware that under the Liverpool Electric Lighting Order of 1891 the Corporation have the option of purchasing the Company's Liverpool business as a going concern in the year 1898. On the enquiry by the Local Government Board as to the extension of the city boundaries, it was agreed that this date should be altered to the year 1900, and that the option should include the Toxteth undertaking also. The Corporation have approached the Board with a view to the immediate purchase of the Company's business, and as they have the right to acquire it at so early a date, the directors do not wish to adopt any obstructive policy, due regard being paid to the interests of the shareholders. The matter is one that naturally demands very careful treatment, and the directors would ask the shareholders to leave it for the present entirely in their hands. Should the Corporation offer terms which appear to the directors to be acceptable, the matter will be laid before the shareholders for their approval. Two directors, Mr. Th. von Sobbe and Mr. D. de Ybarrondo, retire by rotation, and, being eligible, offer themselves for re-election.

BALANCE-SHEET, DEC. 31, 1894.

Dr. Capital and Liabilities.	£	s.	d.

The twelfth ordinary general meeting was held in Liverpool last Friday under the presidency of Mr. Arthur Hill Holme (chairman).

The **Chairman**, in moving the adoption of the report, stated that the Company had had a very good year, and that they might congratulate themselves upon increased business. It was gratifying to find that there had been a steady increase in the number of lamps used—an increase equal to 25 per cent. each year for the past three years. The total number of lights supplied by the Company now was 31,792, and that indicated that the Company was supplying a public want. Whilst recognising the interests of the shareholders, they had not forgotten the customers. When the company started they charged 1s. per unit, which was afterwards reduced to 8d., and subsequently to 7½d. If the Company progressed in the future as it had done in the past, they might yet be able to make a further reduction. He was sure that if they had about double the number of lights they now had, the price could be brought down to something like 5d. They would notice that the expenditure on capital account during the year had amounted to over £40,000. This was accounted for, amongst other matters, owing to the Company having put down more boilers and engines in Highfield-street and some machinery in Oldham-place. The Company had also bought land at both those places, and would therefore have proper room for any extension that might be necessary within the next three years. They had a station at Lark-lane which would be more useful as their system extended, and which at the present time was not a source of loss, although they did not derive profit from it. There was another matter in which they all took a deep interest—namely, the negotiations that they had had with the Corporation. They all knew that the City Council passed a resolution desiring to acquire the undertaking of this Company, and whilst some of the shareholders would probably think that it should be sold, others might think that it should not. However, he must ask the shareholders to leave the matter in the hands of the directors that morning, and say nothing that would give anyone a handle. The directors were giving the matter careful attention, and they and their lawyer, Mr. Radcliffe, had been in communication with the Corporation, and were quite willing to meet them in every way. He asked the shareholders to trust the directors not to sacrifice the property, and yet not to ask too high a price which would make negotiations impossible. So far as the Corporation was concerned, the Company had nothing to fear from them and very little to hope for. The Corporation had never helped them, and everything that they had done had been done in spite of the Corporation. In conclusion, he said that the Company was commenced under difficult circumstances; it had been developed with determination, and even if that should prove to be the final general meeting of the shareholders, owing to the Company being about to die, he thought it would deserve well of their fellow-townsmen.

Sir David Radcliffe seconded the motion, which was unanimously carried.

The **Chairman** moved the payment of a dividend at the rate of 6 per cent. per annum, free of income tax, for the half-year ending December 31, 1894. This was seconded by **Mr. von Sobbe**, and carried.

The proceedings were brought to a close with votes of thanks to the chairman and directors.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY, LIMITED.

The ordinary general meeting of the above Company was held on Tuesday at the offices of the Company, Carnaby-street, Golden-square, Mr. Eustace J. A. Balfour occupying the chair.

The **Chairman**, in moving the adoption of the report and accounts (which we published in our last issue), congratulated the shareholders on the fact that they were receiving 6½ per cent. on the ordinary shares, as against 4½ per cent. in the preceding year. They would require this year to face the question of an increase of plant, as they were near the end of their limit, owing partly to the fact that at Mason's-yard the full output was not obtainable, the Vestry having brought an action against the Company for a nuisance caused by vibration. They proposed to rearrange their machinery at Carnaby-street, and deal with Mason's-yard as the experts might advise. More debentures would be required, but he could not yet say when they would be issued. The cost of working had been reduced during the year by ¾d. a unit, which was creditable to the engineering staff. There had been a large increase in the rates, but the settlement of this matter would have to wait till the next quinquennial valuation of the Vestry. There was one danger ahead in the opposition of the Electrical Supply Corporation, which might reduce the rates so that they would not be remunerative. Efforts were being made to effect a friendly arrangement, and it was to be hoped that a friendly spirit would continue between them. The war of rates had not been commenced by their Company. After referring in appreciative terms to Mr. Kirby, who had resigned his directorship, Mr. Balfour said that during the present year there had been an increase of £1,500 in the gross revenue, they had 26 more customers, and the total number of lamps connected at the end of January was 76,610, an advance of 1,393.

Mr. Latimer Clark seconded the motion.

In reply to questions by shareholders, the **Chairman** stated that no money could be paid on founders' share until the ordinary shareholders had received 7 per cent. With regard to accidents, the Company had only had one, and that a very small one, due to an explosion of gas at the foot of St. James's-street. The Board of Trade and their engineer were seeking a remedy. However, their low-tension system could not produce a shock like the high-

Digitized by Google

tension system. The subject of vibration at Mason's-yard was still being enquired into by the Board of Trade, and it was hoped that the difficulty would be solved.

The motion having been adopted, the **Chairman** moved, and **Mr. Fitch** seconded, the re-election of Mr. G. Balfour and Sir John Morris as directors, which was agreed to, as was the proposal to reappoint the auditors.

NEWCASTLE AND DISTRICT ELECTRIC LIGHTING COMPANY, LIMITED.

The eighth ordinary general meeting of this Company, whose report and accounts were published in our last issue, was held on Monday in Newcastle, Mr. J. D. Millburn (chairman) presiding.

The **Chairman**, in moving the adoption of the report, said that the output of the Company in 1891 was 206,000 units, at a cost of 3·39 per unit; in 1892 it was 290,000, at a cost of 3·11 per unit; in 1893, 388,000, at a cost of 2·63; and in 1894, 431,239, at a cost of 2·45 per unit. Thus while the production had been steadily increasing, the cost had greatly decreased, till it had reached 2·45 per unit, which was the cheapest price at which electricity had ever been produced. As they went on increasing in production the cost would still further decrease, and they would have the satisfaction in time of making a reduction in the price charged to the customers. This continuous reduction in cost of production had not been achieved by any undue capital expenditure as, taking the capital expenditure of the Company in conjunction with the amount of electrical energy produced, it would compare most favourably with any company or corporation in the United Kingdom. The whole of the plant was in a thoroughly satisfactory condition, and it was pleasant to mention that the mains of the Company were in the best possible condition and quite as good to all appearance as the day when they were laid underground. Of course, there would have been some depreciation, but it was not apparent. There were miles and miles of cables, and they were most successful in the manner in which they laid down their tubes and the special joint-boxes. They had a special engine for blowing the air through those mains in order to keep everything perfectly dry and tight. They had great reason to thank the foresight of their managing director (Mr. Parsons) for that, for some of their neighbours had not been so successful in that respect. The condensing plant was doing all that was expected, and, as the operations of the Company increased, all the new machinery could be of the condensing type. In the course of the year they had had their shares quoted on the local stock exchange, and the present price of the shares was placed at a fairly satisfactory figure. The price of the light was cheaper in Newcastle than in any other place in England, and in a year or two they hoped to make it still cheaper. They hoped presently to derive a large income from electricity for cooking purposes. They had not yet got hold of the right motor for driving machinery, hoists, etc., but they believed the time was soon coming when they would get it, and then the finances of the Company would be in a considerably better state in consequence. With regard to the tramways, if the Corporation would allow them to run tramways with overhead wires, as at Milan, Genoa, and many continental cities, they could do it very well and cheaply, but they could not see their way to do it properly by an underground system. That was the reason, perhaps, why they had not taken the matter up. The Chairman then moved the adoption of the report, and that a dividend at the rate of 3½ per cent. for the half-year, making 6 per cent. for the year, be declared.

Sir Benjamin Browne seconded, and the report was adopted, the dividend declared, and Colonel W. M. Angus and Mr. J. B. Simpson re-elected directors.

An extraordinary meeting was then held, at which it was decided to increase the capital from £50,000 to £100,000.

The **Chairman**, in replying to a vote of thanks, paid a high compliment to the officials—Messrs. Parsons, Patterson, and Hunter.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Madrid.—The General Directors of Posts and Telegraphs invite tenders by 19th inst. for 1,000,000 rolls of telegraph paper.

Norwich.—The Town Council require by the 21st inst. tenders for the installation of the electric light at St. Andrew's and Blackfriars Halls. Mr. A. E. Collins, the city engineer, will supply specifications on application.

Weybridge.—The Urban District Council invite tenders for the public lighting of Weybridge on and after September 29. Tenders should state the number of public lights proposed, the illuminating power, and price per light. Tenders should be sent to Mr. Geo. Wheeler, clerk pro tem. to the Council, before 20th inst.

Islington.—Tenders are invited for the supply of alternate-current meters and converters by the Vestry of St. Mary, Islington. Specifications and full particulars may be obained on application to the electrical engineer, 50, Eden-grove, Holloway, N. Applicants will be required to deposit the sum of £1. 1s., which will be returned on receipt of a *bonâ fide* tender.

West Ham.—The Town Council invite tenders for a technical institute and public library in Romford-road, and invite designs for the same. Premiums of £250, £150, and £100 respectively will be paid to the authors of the designs which are placed by the assessor first, second, and third in point of merit. Particulars can be obtained on application to Mr. Fred. E. Hilleary, town clerk, Town Hall, West Ham, on payment of a deposit of £1. 1s., which is returnable. Designs by May 1.

Bury (Lancs.).—Tenders are invited for the supply of lamp-pillars, copper lamps, gas piping and fittings, and glass (perfect) for street lamps, for one year, for the Corporation. Samples may be seen and forms of tender obtained on application to Superintendent Geall, Fire Station Stanley-street. Sealed tenders, endorsed respectively "Lamp-pillars," "Copper Lamps," "Gas Piping and Fittings," and "Glass," to be sent to Mr. John Haslam, town clerk, Corporation Offices, Bury, by 20th inst. Preference will be given to those persons or firms who pay to their workpeople the regular standard rate of wages obtaining at the time in the town or district.

RESULTS OF TENDERS.

Walsall.—The tender of Mr. H. Gough, Dudley-road, Wolverhampton, at £1,750, has been accepted by the Corporation for alterations to buildings at the Wolverhampton-street gasworks, including the construction of boiler-house, dynamo-house, offices, and other works for an electricity generating station.

Wigan.—The committee appointed by the Town Council to invite tenders for electric lighting received the following offers:

Fowler and Co.	£7,931
Brush Company	6,985
Ditto (alternative tender)	8,243
Corlett Electrical Company, Wigan	8,721
Ditto (alternative tender)	8,547
Siemens Bros., London	7,133
Mather and Platt	8,820

The tender recommended for acceptance is that of Messrs. J. Fowler and Co.

South Shields.—The Town Council on the 6th inst. accepted the following tenders:

Black, Hawthorn, and Co., Limited, Gateshead, boilers and pipes	£1,809	0	0
H. Watson and Sons, Newcastle, pumps	905	14	3
S. Z. de Ferranti, Limited, London, engines and alternators	3,003	0	0
India Rubber and Gutta Percha Company, Limited, Silvertown, cables and trenching	4,846	0	0
S. Z. de Ferranti, Limited, London, arc lighting	793	11	0

The section for meters, etc., stands over for the present. The specification for this plant was issued last September. The borough electrical engineer, Mr. Jos. A. Jeckell, determined from the first that the plant to be accepted was that which afforded the best value for the money, and not because the tender happened to be the lowest. In order that he might have the means of comparing the respective merits of the different plants offered which fulfilled the spirit of the specification, irrespective of minor details, firms tendering were requested to submit along with their tenders drawings as per list appended to the specification, and for this reason the time allowed during which tenders were received was much longer than is usually the case. The leading firms submitted the drawings asked for, as it was evident to them that the plant would be considered on its intrinsic construction merits. The tenders accepted were those which in the opinion of the borough electrical engineer offered the best value for the money, and this opinion was endorsed by a sub-committee, consisting of four practical mechanical engineers, subsequently appointed to report to the Electric Lighting Committee on the tenders, and their report was unanimously adopted by the Council. It was decided to put down a rather larger plant than was at first thought of, and the engineer's estimate for this was accepted, and it was resolved to apply to the Local Government Board for leave to borrow £28,000.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,283.

Portrush.—The Watch Committee have decided to establish a telephonic fire-alarm system throughout the borough.

West Cowes.—The surveyor to the District Council has been requested to prepare a scheme for the electric lighting of the town.

Ossett.—A public meeting of the inhabitants of this Yorkshire town has been convened to consider the question of electric lighting.

Rothesay.—The Harbour Trust and Town Council decided on Monday to make enquiry as to the cost of adopting electric lighting at the harbour.

Bell's Asbestos Company.—A dividend of 10 per cent. is announced for the year 1894, £5,000 being placed to reserve, and £3,500 carried forward.

Lambeth.—A special meeting of the Vestry was called for last night to consider, among other matters, the question of abandoning the electric lighting order.

Newport (Mon.).—The Town Council decided on Tuesday to borrow £1,775 for the electric lighting of the Town Hall, markets, baths, free library, and museum.

Exeter.—It is proposed to light the art galleries at the museum by electricity. The matter is under the consideration of the Museum Committee of the Corporation.

Digitized by Google

Dover.—The mains are now being laid at the turret on the Admiralty Pier. It is stated that the electric light will be adopted for the lighthouse at the pierhead.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 10th inst. amounted to £859, as compared with £691 in the corresponding week of last year.

Llanelly.—A report on the proposed scheme, estimated to cost £10,000, of lighting the town by electricity, has been prepared by the borough surveyor. Tenders are to be advertised for.

Great Northern and City Railway.—The capital of the Great Northern and City Railway Company not having been fully subscribed, the directors have decided not to proceed to allotment.

Hastings.—The Town Council have referred back to committee a suggestion that the electric light company should be asked to reduce the amount of the bill on the ground, as was alleged, that the lighting was a failure.

Parish Lighting Company, Limited.—This Company has been registered, with a capital of £15,000, to light with gas, electricity, or other illuminants, the township of Chester-le-Street, Durham, and the neighbourhood generally.

Westminster Electric Supply Corporation.—The ordinary general meeting of shareholders will be held at the offices of the Corporation, Eccleston-place, Eccleston-street, Belgravia, S.W., on Wednesday, the 20th inst., at 11 o'clock in the forenoon.

Mendota Steamship Company, Limited.—This Company has been registered, with a capital of £100,000 in £100 shares, to carry on the business of shipowners, as carriers, contractors for laying telegraph cables, and rendering salvage and towage services.

Folkestone.—Mr. F. H. Medhurst has inspected the district proposed to be electrically lighted according to the proposal of Councillor Baker. The scheme submitted by Mr. Medhurst is estimated to cost £19,000, including the erection of a dust destructor.

Bury.—The Town Council were unable last week to discuss the minutes of the Electric Lighting Committee, who reported that the borough engineer had submitted an exhaustive report on the various schemes and tenders submitted, together with a comparative table.

Monmouth.—It was mentioned at a meeting of the Town Council last week that Mr. Harris, of Messrs. Bramwell and Harris, the consulting engineers to the Corporation, was unable through illness to be present to discuss the sewerage and electric lighting scheme.

Luton.—The Town Council have received a letter from Messrs. Hayward Tyler and Howard, asking to be allowed to send in tenders whenever the Corporation proceeded with their plans for lighting the town by electricity. This has been referred to the Highways Committee.

Black Swan Gold-Mining Company, Limited.—This Company has been registered with a capital of £85,000 to acquire mining property in West Australia, and, among other business, to construct and maintain rail and tram roads, telephones, telegraphs, electric, gas, and water works, etc.

Electric Guest-Call Company, Limited.—This Company has been registered, with a capital of £5,000, to carry on business as manufacturers of and dealers in electrical machines and apparatus; in particular, the production of "announcing clocks" for use in hotels, clubs, and similar establishments.

Wakefield.—Mr. Lee mentioned at Tuesday's meeting of the City Council that it had been decided to engage Mr. R. Hammond as consulting engineer to the Corporation, and to apply for powers to expend £20,000 in carrying out the first instalment of the proposed electric lighting works for the city.

Maxim-Nordenfelt Guns and Ammunition Company, Limited. The general meeting of this Company was held on Monday, when the chairman, Sir Edmund Commerell, incidentally mentioned that the Company had gone into electric work, and that as far as it had gone it had been exceedingly good.

South Africa.—"R. M. B. 202," care of Messrs. Deacon's, Leadenhall-street, E.C., who is a mechanical engineer, is proceeding to South Africa, and is desirous of representing one or more first-class firms of engineers, boiler-makers, or electrical contractors who wish to introduce their manufactures into that district.

City and South London Railway.—The receipts of the Company for the week ended February 10 were £1,022, against £937 for the corresponding week of 1894, or an increase of £85. The total receipts for the current period of the present half-year are £6,041, against £5,727 in the corresponding period of 1894, an increase of £314.

Wandsworth, S.W.—The District Board of Works have resolved that in the event of the electric lighting company commencing works involving the construction of transformer-chambers under the public way in the district, the solicitor should be instructed to apply for an injunction to restrain the company from proceeding therewith.

South Barmouth Freehold Estates Company, Limited.—This Company has been registered, with a capital of £75,000 in £5 shares, for the acquisition of the estates of Ynysfaig and Penrhyn, in the parish of Llangelynin, county Merioneth, and to carry on business as builders, contractors, producers and suppliers of gas and electricity, etc.

Burnley.—In reply to Councillor Bayne, Alderman Collinge stated at a meeting of the Town Council last week that he could not hold out any immediate hope of a reduction in the price of the electric light. It had only just begun to pay its way, and he did not think there was another town similarly situated with respect to coal which charged less than Burnley.

Mining Plant.—It is stated that Messrs. Mather and Platt, Manchester, have now completed the erection of electrical plant at Spitzburg, for the Transvaal Gold Exploration Company, for driving 20 stamps of the Sandycroft type. Much interest is centred in this plant. The dynamos are actuated by a 22in. turbine of 60 h.p., supplied by Messrs. MacAdam Bros, Belfast.

Edison and Swan United.—An extraordinary general meeting of the Edison and Swan United Electric Light Company, Limited, will be held at the Cannon-street Hotel, E.C., on Thursday, the 28th inst., at 3 p.m., to consider and, if approved, to confirm as special resolutions certain resolutions which were passed at the extraordinary general meeting held on the 5th inst., and reported in our last issue.

Neston.—A meeting of the Neston and Parkgate Urban District Council has been held at which, with reference to the proposal to light the district with the electric light, Mr. Grenfell stated that he purposed making a canvass, with a view to finding out who would be willing to take the new illuminant, and eliciting any objections that might be raised, and thus find out whether the project was practical.

Primary Battery.—A non-polarising electric battery, the invention of Messrs. Walker and Wilkins, of Birmingham, has been inspected recently by a party of Liverpool gentlemen. On arriving at the works of the Patent Non-Polarising Voltaic Battery Company, at Springhill Wharf, Birmingham, the party were shown a number of applications of the battery to the production of light and power.

Redcar.—Mr. Bennett and Mr. Stacey, electricians, from Sheffield, have attended a meeting of the Urban Council to explain a scheme for lighting Redcar by electricity, and asking for a concession to lay mains through the streets, the cost to be not greater than the present price of gas, and the town to be at no capital expense. It was decided to hold a special meeting to consider and decide the question.

Edinburgh.—A sub committee of the Edinburgh Town Council had before it on Tuesday applications for extension of the electric lighting system in the South Bridge as far as the Surgeons' Hall, and in the North Back of Canongate. Some conversation took place on the question whether the low-pressure or the high-pressure system should be employed for such extensions, and it was agreed to get a report from Prof. Kennedy on the subject.

Leeds Tramways.—The special sub-committee appointed to prepare a report on the question of tramway haulage held a meeting on Thursday of last week, Alderman Firth presiding. Considerable progress was made with the report, and they expect to complete it at a future meeting. The reasons which have led the Tramways Committee to recommend the electric conduit system for the centre of the city, and the overhead electric system outside, will be fully explained in the report.

Fareham.—The opposition to the purchase of the electric lighting works by the town of Fareham has now reached its culminating point, for the Urban District Council has not only resolved to inform the Local Government Board that it does not desire to proceed with the application for sanction to borrow the necessary £7,000, but also refuses to sanction the payment of an additional sum of £150 to the company until the completion of their contract in September of next year.

Keswick.—The Chairman of the Urban District Council moved at a meeting of the latter that the Council adjourn for the purpose of receiving the reply from the electric light company. Mr. Pape moved, and Mr. Mumberson seconded, that the reply be considered at the next monthly meeting. The Chairman said if they did not agree to his resolution, he could get over the difficulty by calling a meeting by requisition. The Chairman eventually withdrew his resolution, and Mr. Pape's proposition was agreed to.

Clerkenwell.—The Vestry have received a letter from the Board of Trade, forwarding the copy letter they have addressed to the London County Council, on the subject of transformer-chambers, to which reference has previously been made in our columns. A letter was also read from the Vestry of St. George-the-Martyr, Southwark, expressing the hope that the Board of Trade will not adopt the recommendation of Sir Courtenay Boyle, contained in the foregoing letter. This was referred to the Parliamentary Committee.

Acton.—The Urban District Council have had under consideration the question of the advisability of assenting or dissenting to the application of the London United Tramways Company to the Board of Trade for a provisional order authorising them to extend their line to Acton-hill and conferring on the company certain other powers. A letter was read from Mr. Clifton Robinson on behalf of the company, and a deputation of ratepayers was heard in support of a petition in favour of the scheme. Another deputation was heard on the other side. Consideration of the matter has been adjourned.

City of London Electric Lighting Company.—Mr. J. Cecil Bull, the manager and secretary of this Company, informs us that the Board have resolved, subject to the completion of the audit, to recommend to the shareholders the payment of the following dividends for the past half-year: at the full rate on the 6 per cent. preference shares, and 5s. per share on the ordinary shares, being at the rate of 5 per cent. per annum. The transfer-books and register of members of this Company are now closed to the 27th inst. for the purpose of preparing warrants for dividends on the preference and ordinary shares.

Digitized by Google

Ambleside.—A meeting of the District Council has been held, at which Mr. Hunter proposed that steps should be taken to oppose the Windermere and District Electric Lighting Company getting a provisional order. He thought it advisable to oppose the order, and followed by giving a number of quotations as to the cost of working the electric light, and showed that local authorities could do it cheaper. The Chairman said the question was one of opposition, and not so much the cost of working. A committee was elected to look into the matter.

Liverpool.—A meeting of the Special Lighting Committee of the City Council was held on Monday, Alderman Fred Smith presiding. No statement was made with regard to the rejection of the resolution by the Council at its last meeting, by means of which the special meeting convened for the consideration of the question of acquiring the Electric Supply Company's undertaking was countermanded, but the proposal to purchase the company's property was again discussed, and negotiations of an important character are in progress. The members of the committee do not think it advisable to disclose the nature of these negotiations at present.

Bath.—The Town Council have agreed, on the motion of Alderman Sturges, seconded by Mr. Knight, to pay the electric light company the £11. 5s. which might have been deducted because of the failure of one circuit of the light during November. Alderman Sturges said since the bill had been under consideration they had consulted Mr. Gatehouse, who gave it as his opinion that the failure was owing to the flood. The gas lights were out all over the city, and they thought it would be exceedingly ungenerous and unjust to make the electric light company pay while the gas company got off without paying a penny, while their lamps were not alight at all.

Manchester.—Alderman Gibson, in moving the adoption of certain recommendations at a meeting of the City Council last week, expressed the opinion that the Council had acted wisely in placing the gas and electric light undertakings under the direction of one committee; for otherwise these two enterprises, which in their separate spheres were capable of helping each other, would have become severe competitors. The committee proposed to reduce the price of the electric current from 8d. per unit to 6d. to small consumers. They also wished to do away with the charge for the hire of meters, and to lower the price of gas used for other than illuminating purposes.

St. Olave's, Southwark.—The Lighting Committee of the Board of Works recommend that the Board refuse their consent to the provisional order of the County of London and Brush Provincial Electric Lighting Company, Limited, in respect of the district of St. Olave's Board of Works. Mr. Fells moved the adoption of the committee's recommendation. Mr. Lafone thought it was essential that they should have competition for the electric lighting of the district, so that the light could be obtained at a reasonable price. At present they were paying anything but a reasonable price. Eventually it was decided to consent to the provisional order, subject to clauses being inserted to the satisfaction of the Board.

Southport.—The monthly meeting of the Town Council was held on Tuesday, when a long discussion took place on the minutes of the Electricity Committee with reference to the tender of Mr. Thos. Bridge to erect the extensions to the engine and boiler house of the electricity works for £1,897, which tender had been accepted by the committee, though a tender lower by £138 than this had been received. Councillor Hulme said that there were cases where the lowest tenders were the best. Alderman Hacking commented in severe terms upon the action of the committee, and said he would move that the lowest tender be accepted. Eventually it was decided to discuss the matter in General Purposes Committee.

Glasgow.—A complaint was made at a recent meeting of the Town Council by Mr. J. W. Dick, who asked if the same method of lighting was to be followed with the remainder of the tramway cars. Mr. Walter Paton said the electric lighting of the cars had not been so successful as they would have liked. They expected that the whole of the cars would have been lighted during the current winter, but they had found this impossible. Altogether, about 130 cars would be lighted, and the idea was that before the beginning of next winter the remaining 170 cars would be fitted up with the electric light. The point Mr. Dick had mentioned required consideration, and he had no doubt the committee would endeavour to bring about an improvement.

Hammersmith.—A discussion has arisen at a meeting of the Vestry with reference to a suggestion to light Uxbridge-road, from the centre of the road by electricity. Mr. Cramp condemned the suggestion, which he described as premature. Mr. Glasier agreed that it was premature to refer this matter to the Electric Lighting Committee, as it was not likely to effect an introduction of electric light into the parish for at least two years. Mr. Searle, referring to the tram lines, said there ought to be 5ft. between the two sets of rails in the centre of the road. If the lines were relaid as at present, and the Vestry decided to erect electric standards in the centre of the road, the rails would have to be removed. A proposition to refer this matter to a committee was lost.

Brighton.—The Lighting Committee have reported to the Town Council that they had instructed the manager to carry out the installation of the electric light at the swimming-bath in North-road. At a subsequent meeting it was resolved that two additional lamps be erected in Hampstead-road, and a letter from Councillor Fowler forwarding a memorial requesting that lamps may be erected in Edburton-road was referred to the borough surveyor. The proceedings having been moved by Councillor Stafford, Councillor Dell expressed anxiety to know whether proper precautions had been taken against the electric lighting wires and the gas-pipes coming into contact and occasioning explosions. The Mayor having reassured him on this point, the report was adopted.

Southwark Bridge Explosion. — Referring to the recent explosion on Southwark Bridge, Mr. George Livesey stated, at a meeting of the South Metropolitan Gas Company on Wednesday, that there had been an excavation beneath their main—formerly belonging to the Phœnix Company—which might have been laid for 40 years. Some work had been done by the City authorities to their sewers, and the main was excavated under, and was then left unsupported. This caused the fault to occur. The gas could not escape into the air, and probably it percolated through the loose earth into the electric light conduits. How it ignited, however, he could not say. He had mentioned this to show that the company were quite alive to these matters and the difficulties against which they had to contend.

Hawkshead.—The District Highway Board discussed last week some correspondence with the electric supply company, who, it was reported, declined to give any guarantee that they would lay a cable throughout the length of the Board's district. Mr. Marshall said that the request of the Board had been considered by the committee of the Rural District Council, but the Board's application came in rather late, and it did not appear that they were likely to receive much assistance. However, the promoting company had agreed to insert a clause to the effect that they shall, on the request of the owners of property in a district, within six months, lay down a distributing main through any part of the district, so as to offer a supply of electricity if the people give a guarantee for a period not less than three years.

Cheltenham.—A meeting of the Town Council has been held at which Mr. Norman, in proposing the adoption of the Electric Light Committee's minutes, explained that the delay in proceeding with the works was due to the weather. The committee could not afford to light the library free of charge. The committee, in addition to charging only £50 per annum for the supply to the library, were also prepared to pay any gas bill incurred through the failure of the electric light. Mr. Lewis hoped that the claimants for compensation owing to accidents due to the works would be met in a fair spirit, so that the Council should not be involved in any risky litigation. Mr. Norman, in closing the discussion, mentioned that the system for the first month would be worked at the risk of the contractors. Every precaution had been taken to guard against explosions. The minutes were confirmed.

York.—A question was asked by Captain Lindberg at a meeting last week of the York United Gas Company as to whether the directors had ever given any consideration to the question of procuring rights for lighting the city by electricity. Some four years ago the Corporation obtained powers of this kind, but up to the present nothing had been done. It would, in his opinion, be greatly to the advantage of the company if they obtained powers, as they would then have the entire management and control of the whole of the lighting of the city, instead of the Corporation having one portion and the company another. The Chairman said the directors were obliged for the suggestion. They did not turn a deaf ear to it, and in due course it would be attended to. There were legal difficulties in the matter, but it should have their consideration.

Queenstown.—The Town Commissioners met last week to hear a report from Mr. Hammond, M.I.C.E., on the practicability of lighting Queenstown by electricity. Mr. Hammond said he believed from what he had seen it would be practicable to light Queenstown most successfully, and at a reasonable figure. He believed it would be a great saving to the ratepayers of the town, as the price charged for gas was very high indeed. However, he presumed the Commissioners were anxious to see any scheme introduced a success, combined, of course, with economy, and he would be well pleased to give them any information he might possess on the subject. After hearing Mr. Hammond's views, it was decided that he should send a written report to the Board, and be consulting engineer if the scheme were adopted. Mr. Hammond then stated that he would visit the waterworks in company with their engineer, Mr. Campbell, to inspect the machinery at the pumping station, as well as to inspect the town generally, and he would send in his report on as early a date as possible.

Leeds.—The Yorkshire House-to-House Electricity Company announce a further reduction in the charges for current. Commencing on July 1 next, the price per Board of Trade unit will be as follows: when the consumption for the quarter does not exceed 1,500 units, 6d.; when the consumption for the quarter exceeds 1,500 and does not exceed 3,000 units, 5½d.; when the consumption for the quarter exceeds 3,000 units, 5¼d. These prices will be subject to discount based upon the number of hours per quarter during which the current is used, each consumer being called upon to declare the maximum number of lights required to be in use at any one time. The scale of discounts ranges from 5 to 15 per cent. In addition to the discounts accruing under this arrangement, a discount of 5 per cent. will be allowed on the net amount of accounts paid within one month from the date o rendering, and 2½ per cent. on accounts paid within two months. For heating, cooking, and power purposes current will be supplied at 3d. per Board of Trade unit.

Reading.—The Town Council have adopted a resolution referring to a committee the question of the best method of providing some uniform system for artificially lighting the entire block of

Digitized by Google

public buildings, including the proposed new buildings for an art gallery and for the extension of the free library and museum. It is estimated that to light the whole of the buildings by electric light would cost £500 a year, and Alderman Messer stated last week at a meeting of the Council that it was a question whether for that sum they could not lay down their own plant. The Town Council intend to light the general market by electricity. The Reading Electric Supply Company announce that they will shortly be able to supply electricity to consumers occupying premises in the following streets: Broad-street, Blagrave-street, Butter Market, Caversham-road (to Vastern-road), Duke-street, Friar-street, High-street, King's-road (to Crown Bridge), London-street, Minster-street, Market-place, North Forbury-road, Oxford-road (to Howard-street), the Forbury, Vastern-road, and West-street. The charge for the electrical energy will be 8d. per unit.

Rochdale.—When the minutes of the Health Committee were under discussion at a meeting of the Town Council last week, Councillor Diggle enquired whether any action had been taken in regard to a suggestion in the minutes that the Electric Lighting Sub-Committee should promptly consider the question of utilising the surplus steam power at the sanitary works for the purpose of generating electricity. He also asked whether the putting in of new boilers at the sanitary works had been a success. The Mayor, as chairman of the committee, said the electric lighting question had yet to be considered by the sub-committee, which had not had a meeting since the suggestion alluded to was made The new boiler scheme had been more successful even than the Health Committee anticipated. Councillor Cunliffe said he did not think the Council fully appreciated the power available at the sanitary works since the introduction of the new furnaces. There was power enough now going to waste to enable the Electric Lighting Sub-Committee, if they would only come together, to light up the Town Hall, the esplanade, and the free library. The Mayor said this question had been put into the hands of a sub-committee, and he thought their report should first be awaited.

Wigan.—The committee appointed to consider the question of a supply of electric light have reported that invitations were sent to five firms to prepare a scheme with specification and cost of laying down electrical plant for the supply of current over one part of the borough. The firms were Messrs. John Fowler and Co., Leeds; the Corlett Electrical Engineering Company, Wigan; Messrs. Mather and Platt, Manchester; the Brush Electrical Engineering Company, London; and Messrs. Siemens Bros and Co., London. It was pointed out to the representative of the respective firms that, although the committee defined the area for an "immediate installation," there was every probability that ere long this would have to be extended. The committee have met on several occasions for the purpose of analysing and discussing the five schemes in all their bearings, and come to the conclusion to recommend the scheme as propounded by Messrs. Jno. Fowler and Co. as being the most suitable. The scheme recommended is based on the employment of the alternating-current system. Having decided on the scheme to be adopted, the committee have asked for instructions to proceed, or otherwise, with the preparation of drawings, etc., for the erection of boiler-house and boiler seatings, engine and dynamo house, with foundations for engines and dynamos, testing and store rooms, and offices. The Town Council have decided to apply to the Local Government Board for sanction to borrow £20,000 for the purposes of electric lighting. The tenders are further referred to in our contract columns.

Tunbridge Wells.—The Lighting Committee of the Town Council have reported that they have received an application from the National Telephone Company for permission to lay their wires underground in the trenches in which the electric lighting mains are to be laid, from Grosvenor-road to High-street. The committee have arranged that the company shall pay down a sum of £50 towards the cost of the trenches, and an annual rent of £5. The report was adopted. The committee also reported that they had held three meetings. The position of the arc lamps in the streets was provisionally decided. Messrs. Burn and Berridge wrote alleging that the electric lighting mains in London-road had been laid in small portions of the Common without permission. The town clerk was instructed to reply that the committee had throughout endeavoured to avoid any possibility of dispute with the manorial authorities, and had not laid the mains in any place requiring their consent. It was also decided, in view of future contingencies, to take counsel's opinion. Mr. Preece reported that he had selected sites for having transformer stations at Grosvenor-corner, Mount-pleasant, High-street, and Parade, and the surveyor was instructed to prepare specifications and invite tenders from local builders. Mr. Beale wrote suggesting that the mains should be extended as far as Eridge Station, and Mr. Hills asked for a supply in Crescent-road. It was decided that on completing the work in hand applications for extension should be favourably considered, and that the guarantee required for each extension should be considered on its merits.

Isle of Man Tramways Company.—The report of the Isle of Man Tramways and Electric Power Company, Limited, for 1894, states that the available profit from May 1 to December 31, including £526 premiums on shares sold, amounted to £11,034. Out of this an interim dividend of 6 per cent. per annum on the preference and 7½ per cent. per annum on the ordinary shares, amounting to £4,214, was paid for the six months ended October; £1,667 interest on debentures, up to the end of December, and £43 interest on mortgages (balance); making a total of £5,924. The directors recommend that a further dividend at the rate of 6 per cent. per annum on the preference, and 7½ per cent. per annum on the ordinary shares, for the remaining portion of the financial year ending December, amounting to £1,437, be now declared; that £2,000 be carried to a reserve and renewal fund; and that the balance of £1,673 be carried to profit and loss new account. Owing to unavoidable delays, the passenger traffic between Groudle and Laxey was not commenced until July 28, and this part of the line being the most important section, the profits are much less than what may be anticipated in future years. The passenger traffic on the electric line during the winter months has exceeded the expectations of the directors, who are confident that the revenue to be derived from goods and merchandise traffic will be substantial. Arrangements are being made to meet the wants of the districts through which the tramway passes, together with the surrounding neighbourhoods. After providing for the dividends on the preference and ordinary shares, and interest on debentures up to December 31, and carrying £2,000 to the reserve and renewal fund, an available sum of £4,080 over and above the balance carried forward remains in hand to meet any necessary outlay on rolling-stock, etc.

Cardiff.—During the consideration of the minutes of the Electric Lighting Committee at Monday's meeting of the Cardiff County Council, Councillor Trounce enquired how there came to be a loss of £3,500 in one year on the electric lighting works. He asked if anything could be done to increase the revenue. The Mayor said the committee was doing all it could in the matter to induce a larger number of tradesmen and others to adopt the new method of lighting, and it was hoped that the number of new customers would steadily increase. Councillor White moved that the appointment of Mr. Franklyn as engineer be not confirmed by the Council. The appointment must, in accordance with resolution, be advertised, and he proposed that it be advertised. Councillor Crossman seconded the motion. The Mayor said they had only half a load on the machinery, and it was too strong for the position, but when the load became greater the vibration which was now taking place would subside. He was so informed by Mr. Massey, their engineer, and he understood that Mr. Harpur confirmed him. Mr. Harpur intimated that he did not confirm the statement. The Mayor said they were in the awkward position of having no one in absolute authority at the works. There was a division of opinion between the engineers, and it was too much to expect Mr. Harpur, with his other duties, to attend to the electric lighting works. Mr. Franklyn had come down to take charge for Messrs. Siemens, who were putting in very valuable plant. The engineer they had appointed at £150 a year had declined the post, Cheltenham having paid its engineer £250 per annum. There were four engines, four engine drivers, and four stokers, but so far only two engines had been running. The committee must have a free hand to appoint someone who was thoroughly qualified, and they could not get such an engineer at less than £200 a year. The minutes of the committee on this point were referred back, and it was resolved that the appointment be advertised. On the motion of the Mayor, seconded by Councillor Good, it was resolved that the borough engineer and Mr. Massey prepare a full statement each with regard to the further improvements necessary at the works and with their own recommendations.

Bradford.—Mr. W. C. Dixon (chairman of the Gas and Electricity Supply Committee) moved the adoption of the minutes of that committee at Tuesday's meeting of the Town Council. Mr. Dixon asked the Council to sanction the purchase of two new engines for the electricity works—a matter that was not referred to in the minutes. He said that a sub-committee had unanimously passed a resolution in favour of getting two new engines, and he asked the Council for sanction to the proposal out of the ordinary course in order to save time. The electricity works were running at their fullest capacity, and it was urgent that the additional power should be obtained with as little delay as possible. Some time since arrangements were made to get two new boilers, which but for the severe frost would probably now have been at work. Unless the two new engines were obtained the money spent on the boilers would be practically wasted. He hoped the Council would pass the proposal. It would be two or three months before the engines could be got to work. Mr. James Kay seconded the motion. Mr. T. Crossland said that in two or three months they would be in the midst of summer, and he therefore did not see the necessity for hurrying the matter. Alderman Morley, Mr. R. Pratt, and Alderman W. Lister expressed the opinion that in view of the impossibility of getting the new engines to work till the year was much further advanced, it was unnecessary to hurry the matter through the Council. Mr. W. E. Aykroyd asked what kind of engine it was intended to order. Mr. Dixon said he did not think there was another electrical engineer in England who had been placed in such difficulties as Mr. Baynes. The department had been working from hand to mouth ever since the electrical station was started, and he wished to relieve Mr. Baynes of the unnecessary anxiety thus imposed on him. It would take a long time to get out specifications and get in tenders. The committee were not tied down to any particular class of engine. He had his own opinion as to the class of engine required, and at the proper time he would not hesitate to give that opinion. It would take the committee all their time to get the engines running by next winter, and Mr. Baynes assured him that before the summer was over he would have all the work which the present station would do. Six weeks ago there was a breakdown, for which it was claimed that the Corporation were responsible, mainly because there were no spare engines. He thought precautions ought to be taken for the future, and that some spare plant ought to be provided. Ultimately Mr. Dixon withdrew his proposition for the purchase of engines.

PROVISIONAL PATENTS, 1895.

FEBRUARY 4.

2394. **Improvements in primary batteries.** Hymen Levetus, Edward Moses Levetus, and Walter Rowbotham, 47, Vittoria-street, Birmingham.

2430. **Improved means for insulating electric conductors.** George Gatton Melhuish Hardingham, 191, Fleet-street, London. (The firm of Felten and Guilleaume, Germany.)

2446. **Improvements in apparatus for the reflection of electric or other light applicable for use in connection with buoys at sea, signalling, advertising, and other purposes.** John Boyes, 124, Chancery-lane, London.

2450. **Improvements in the bulbs of incandescent lamps.** Alexander Leslie Fyfe, 22, Southampton-buildings, Chancery-lane, London.

FEBRUARY 5.

2492. **Improvements in submarine telegraph cables.** William Sharpey Seaton, 124, Chancery-lane, London.

2541. **Improvements in electric burglar alarms.** Lionel Herbert Hordern, 70, Chancery-lane, London.

2558. **Improvements in electric arc lamps.** Oliver Leopold Peard and Albert Essinger, 55, Chancery-lane, London.

2561. **Improved means and appliances for regulating the feed of carbons in electric arc lamps.** James Jeffryes and John Lea, 166, Fleet-street, London.

FEBRUARY 6.

2570. **Improvements in chandeliers, electroliers, pendant hanging lamps, and brackets for gas, oil, or electric light.** Charles Meason and Thomas Ford, St. Ives, Crompton-road, Handsworth, Birmingham.

2604. **Improvements in electric arc lamps and their connections.** Rookes Evelyn Bell Crompton, 55, Chancery-lane, London.

2606. **Electrical and pneumatic apparatus for scraping, cleaning, and lubricating the hulls of ships when afloat or in dock.** Alfred William Gatfield and William Richard Clark, 9, Station-terrace, Greyhound-lane, Streatham Common, London.

2650. **Improvements in electric bells or gongs.** Samuel Quincey, 567, Seven Sisters-road, South Tottenham, London.

2659. **Improvements in electrical resistances.** Sir Charles Henry Augustus Frederick Lockhart Ross, Bart., 6, Bream's-buildings, Chancery-lane, London.

FEBRUARY 7.

2675. **Improvements relating to insulators for overhead electrical conductors.** Arthur Wiglesworth, 10, St. George's-crescent, Liverpool.

2740. **Improvements in dynamo brushes.** Thomas Fryer and Albert E. Channon, 5, Hatton garden, London.

FEBRUARY 8.

2804. **Metallic mixtures and alloys for effecting electro-chemical decompositions.** Oliver Imray, 28, Southampton-buildings, Chancery-lane, London. (L. Diehl, Germany.)

2805. **To regulate or assimilate the movements of electrically-connected mechanical instruments or machines, more particularly wheels or other bodies revolving upon axes, and to diminish variations in the movements or speed of the same by means of electrical impulses.** Richard Joseph Crowley, Harry William Charles Cox, and Clarence Frank Leighton, 2, Clement's-inn, Strand, London.

2808. **Improvements in electric cables.** William Phillips Thompson, 31, High Holborn, London. (Franz Clouth, Germany.)

2816. **Improvements in secondary batteries.** Frank King, 47, Lincoln's-inn-fields, London.

2817. **Improvements in or connected with electrical conductors for heating purposes.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

2827. **Improvements in primary batteries.** Charles Lucien Charlopin, Vincent Marie Cornély, and Louis Charles Henry Dautelf, 70, Palace-chambers, Westminster.

FEBRUARY 9.

2874. **Improvements in or connected with electric lamps for surgical operations.** William Henry Buckley, 57, Barton-arcade, Manchester.

2883. **A new or improved process to render the liquid of primary or secondary batteries motionless.** Auguste Lesquoy, 70, Palace-chambers, Westminster.

2894. **Improvements in the production of zinc chloride and in the generation of electricity.** Richard William Hill, 97, Newgate street, London.

2913. **Improvements in series parallel controllers.** James Devonshire, 24, Southampton-buildings, Chancery-lane, London. (Edward D. Priest, United States.) (Complete specification.)

2914. **Improvements in systems of electrical distribution.** James Devonshire, 24, Southampton-buildings, Chancery-lane, London. (Charles P. Steinmetz, United States.) (Complete specification.)

2915. **Improvements in systems of distribution by alternating currents.** James Devonshire, 24, Southampton-buildings, Chancery-lane, London. (Charles P. Steinmetz, United States.) (Complete specification.)

2916. **Improvements in systems of electric distribution.** James Devonshire, 24, Southampton-buildings, Chancery-lane, London. (Charles P. Steinmetz, United States.) (Complete specification.)

2917. **Improvements in systems of electrical distribution.** James Devonshire, 24, Southampton-buildings, Chancery-lane, London. (Charles P. Steinmetz, United States.) (Complete specification.)

2918. **Improvements in windings for dynamo-electric machines.** James Devonshire, 24, Southampton-buildings, Chancery-lane, London. (Charles P. Steinmetz, United States.) (Complete specification.)

SPECIFICATIONS PUBLISHED.

1894.

3109. **Electric locomotive.** Imray. (Rinecker.)

3294. **Electric lighting apparatus for gas-burners.** Peterson.

4366. **Dynamo-electric machines.** Boult. (Compagnie de l'Industrie Electrique)

5314. **Magnetic separators.** Anderson.

5721. **Electrolytic decomposition of common salt.** Smith. (Jorgensen.)

18217. **Transmitting telephonic messages between shore and lighthouse, etc.** Blake.

21353. **Electric, etc., motors for railway vehicles.** Park.

21629. **Electric railways.** Hanisch and others.

24234. **Electric lighting reflectors.** Körber.

24374. **Insulation of electric wires or cables.** Clouth.

24431. **Telegraph, etc., posts.** Siemens Bros. and Co. and Perry.

24630. **Dissociating soluble salts by electrolysis.** Blackmore.

NOTES.

New Calendar.—Messrs. Ernest Scott and Mountain, Limited, have sent us a calendar for 1895.

Northern Society of Electrical Engineers.—The council have elected Mr. S. Z. de Ferranti a vice-president of the society in place of the late Mr. G. E. Preece.

Electric Bells.—The division electric bells failed to act in the House of Commons one day last week. Such was, however, not the case at Drury-lane pantomime.

Paris Exhibition.—The *Revue Industrielle* suggests the construction of electric tramways in Paris for the transport of visitors to and from the exhibition to be held in that city in 1900.

New Rectifier.—It is announced that Messrs. Ganz and Co., of Budapest, will shortly introduce a new rectifier having the property of transforming an alternating current into a constant continuous current.

Electric Tanning.—We have received a copy of a paper read last month by Mr. L. A. Groth before the Society of German Leather Manufacturers descriptive of his system of tanning by electricity.

Society of Arts.—On Wednesday next, at 8 p.m., a paper on "Furnaces for Roasting Gold-Bearing Ores," by Mr. C. G. Warnford Lock, will be presented. Prof. W. C. Roberts-Austen, C.B., F.R.S., will preside.

Steam Tramways in Italy.—The Institution of Civil Engineers have just issued an illustrated paper on "Steam Tramways in Italy," by Mr. P. Amoretti, manager of the Steam Tramway Association, Turin.

Building Trades' Exhibition.—A proposal is under the consideration of the Consultative Council of this exhibition for the purposes of having lectures delivered at the exhibition on electricity in building operations.

Electricity on Warships.—The "Barfleur," which has been selected to replace the "Sans Pareil" in the Mediterranean, has been fitted with electric gear for working her guns, which has given the utmost satisfaction.

Municipalisation of Tramways.—The London County Council Tramways Bill was read a second time in the House of Commons on Tuesday. A Bill to facilitate the working of tramways by local authorities has been issued.

Medals for Bravery.—The London County Council on Tuesday awarded their silver medal for extraordinary bravery to Firemen F. Bishop and W. J. Tizard in connection with the recent fire at Kensington Court electric light station.

Waterloo and City Railway.—The City Commission of Sewers on Tuesday approved a plan and section of the proposed works of the Waterloo and City Railway from Blackfriars Bridge (underneath Queen Victoria-street) to Queen-street.

Red Sea Cable.—The French Chamber of Deputies have adopted the credit of 1,800,000f., or, say, £72,000, for the laying of a cable between the French Red Sea port Obock and Djibouti, the southernmost point of the French territory on that coast.

The Ferranti Effect.—This phenomenon was discussed by Mr. Carl Pichelmayer before a recent meeting of the Vienna Electrotechnical Society. The paper, which is treated mathematically, is published in the *Zeitschrift für Elektrotechnik* of February 15.

Rating of Machinery.—The second reading of the Rating of Machinery Bill was moved on Wednesday in the House of Commons by Sir W. Houldsworth. It was carried by a majority of 51. The Bill was referred to a Grand Committee by a majority of 36.

The Kensington Fire.—A verdict of death from suffocation was returned in the case of the child who met her death in connection with the fire at Kensington Court station last week. The jury stated that there was not sufficient evidence to show how the fire originated.

Having a Drop.—It appears from figures published that the consumption of coal gas in Paris during 1894 diminished by approximately 3,000,000 cubic metres as compared with the previous year. No doubt the increase in the use of the electric light has contributed to this result.

The Day Load.—In referring to a paper read recently before the Société Internationale des Electriciens on the Hermite system of sanitation, a French contemporary suggests that the method should prove of great benefit to supply companies in the direction of providing them with a day load.

Price-List.—Mr. Severin Senator, 128, Wilhelmstrasse, Berlin, S.W., sends us price-lists of incandescent lamps, arc lamps, and carbons. He also informs us that his business comprises all branches of electrical applications, especially electric light installations, and all material and accessories for the same.

Cable Communication with Lightships.—The General Purposes Committee of the Canterbury Corporation have decided to send a letter to the Board of Trade asking them to accelerate as far as possible the establishment and extension of electric cables between the lightships and the shore.

Hawaiian Cable.—A Reuter's telegram from Washington, dated 19th inst., says that the conferees of the Senate and the House of Representatives are unable to agree as to the item of 5,000,000dols. for beginning the laying down of the Hawaiian cable, and that a further conference has been ordered.

Institution of Electrical Engineers.—The discussion will be resumed on Thursday next of the paper presented last week by Mr. W. B. Sayers, associate, on "Reversible Regenerative Armatures and Short-Air-Space Dynamos." The paper and discussion thereon at the meeting on the 14th ult. were given in our last issue.

Telephony in Russia.—It is stated that the Russian Government have granted concessions for 20 years for the establishment and working of telephone exchanges in 11 towns. The Government will receive 10 per cent. of the net receipts, and the telephone systems will become the property of the State at the expiration of the 20 years.

Regulations for Installations.—A few weeks ago we published a translation of the fire insurance regulations drawn up by the Technical Committee of the Berlin Electrotechnical Society. These regulations were discussed at a meeting of the society on 22nd January, when various proposals were made for alterations in the projected rules.

Electric Railways in London.—The Parliamentary Committee of the London County Council on Tuesday recommended that a petition be sealed and presented, if necessary, against the London, Walthamstow, and Epping Forest Railway Bill, but that no action be taken with regard to the City and South London Railway Bill and the Great Northern and City Railway Bill.

Institution of Civil Engineers.—The discussion will be resumed on Tuesday next of the paper by Messrs. Butters and Smart, on "Plant for the Extraction of Gold by the Cyanide Process"; and, time permitting, papers will be read on "Electric Haulage at Earnock Colliery," by

Digitized by Google

Mr. Robert Robertson, B.Sc., M.I.C.E.; and on "Electricity Applied to River Gold-Dredging," by Mr. Robert Hay, M.I.C.E.

Gas-Engine Competition.—It appears that the projected competition of gas-engines, to which we referred a few weeks ago, and which was promoted by the Société Technique de l'Industrie du Gaz, has completely collapsed. A circular to this effect has been issued by the society, who state that this decision has been arrived at in consequence of there being only six entries, including the Niel, Crossley, and Charon gas-engines.

Cable Rates to South Africa.—A telegram from Pretoria states that the negotiations between representatives of the South African States and the cable companies for the reduction of the cable rates between England and South Africa have reached an important stage, the Transvaal Government having agreed to pay an annual subsidy of £10,000 for 15 years provided the tariff be reduced from 8s. 11d. to 5s. per word.

Telegraphic Arrangements. — The Newcastle Chamber of Commerce on Wednesday decided to recommend the National Association of Chambers, meeting in London next month, to urge upon the Government the necessity of immediately placing telegraphic intercommunication between commercial and seaport towns in such a position as to render interruption by storms no longer possible.

Royal Institution.—The Right Hon. Lord Rayleigh, F.R.S., professor of natural philosophy in the Royal Institution, will deliver a course of six experimental lectures on "Waves and Vibrations," at the Royal Institution, on Saturdays, March 2, 9, 16, 23, and 30, and April 6. His lordship will also deliver the Friday evening discourse on April 5, when his subject will be, "Argon, the New Constituent of the Atmosphere."

Gas-Engines for Electric Lighting.—A communication was read by M. V. Langlois before a recent meeting of the Société des Ingénieurs Civils de France dealing with the industrial application of gas-engines, particularly for electric lighting. The author showed that it is more advantageous to use a gas-engine to drive a dynamo for the production of light than it is to utilise the coal gas direct for illuminating purposes.

Institution of Junior Engineers.—To-morrow (Saturday) the members of this society will visit the works of Messrs. Siemens Bros. and Co., at Woolwich, where they will be received by the president, Mr. Alex. Siemens. The train conveying the visitors will leave Charing Cross at 9.20 a.m. On Friday next, March 1, a paper by Mr. A. H. Newsam Smith, on "Locomotive Repairing Works," will be read at a meeting to be held at the Westminster Palace Hotel.

Personal.—The St. Pancras Vestry have appointed Mr. Thos. Cooper, M.A., late of Oxford, assistant engineer at the Regent's Park electric light station.—Mr. George Duffitt, who was for many years connected with the Edison and Swan Company, has been appointed by Froggatt's Electric Lighting Company, Limited, to proceed to Glasgow to take charge of the lighting of the Corporation tramcars, and to fit up a charging station at Coplawhill.

American Report on Units and Standards.—The January issue of the *Transactions* of the American Institute of Electrical Engineers contains the report of the Committee on Units and Standards, together with a printed copy of an Act—passed in July last—defining and establishing units of electrical measurement in the United States. The report is practically identical with that published in our issue of August 24, 1894, page 222, to which we refer our readers.

Card of Electrical Engineering Plant.—An attractive speciality card has been brought out by Messrs. Ernest Scott and Mountain, Limited, Newcastle-upon-Tyne. One page illustrates a variety of steam-engines, pumps, and fans; the second shows machinery for the electrical transmission of power; and the third represents plant for electric lighting. In fact, the card shows in brief a number of the company's manufactures, besides containing a calendar for 1895.

New York "Electrical Review."—No, no, dear *Electrical Review*, you have been wool-gathering, and no wonder can therefore be expressed at your missing the point. We always leave to our contemporaries the pleasant duty of padding out their columns with what is of no earthly interest, confining our remarks to briefly stating the facts of any particular case. So, of course, we left the lack-of-interest Brooklyn strike to them—and to you. Do you feel better now?

The Proposed Pacific Cable.—An Ottawa cablegram, dated February 15, says that the Minister of Trade states that the lowest tender for laying the Pacific cable has been received from a London firm, the amount being £1,517,000. The route proposed is from Vancouver to Fanning Island, Fiji, and Norfolk Island, the cable dividing at the last-named place into branches to New Zealand and Australia. The amount of the tender is about half the estimate made by the British postal authorities.

New Method of Cable Jointing.—A reliable method of jointing one end of a cable to another or to an end contact (cable shoe) is described by Mr. K. Feussner, of the Physikalische Technische Reichsanstalt, Charlottenburg, in the *Electrotechnische Zeitschrift* of January 31. The system consists in stripping the insulation off the cable end and placing over the latter a thin copper collar, so that the whole can be mechanically compressed together. The newly filed cross-section of the cable can then be easily soldered.

Electrometallurgical Work in France.—Several proposals were brought before a recent meeting of the Société Electrométallurgique Française of Froges and were adopted. One was to amalgamate the company with the Société Française de l'Alumine Pure, so as to place the company in a better position to obtain aluminium; the second was to allow the Neuhausen Aluminium Works to become large shareholders in the company; and the third was to increase the capital of the company by £128,000.

Mechanical Traction.—It was mentioned by Mr. E. M. Underdown, Q.C., at a meeting on Tuesday of the Tramways Union Company, who have lines in Bremen, Bucharest, and Madrid, that there was no doubt that animal traction was a very expensive method, and that the question was whether they could have any reasonable chance of success by substituting mechanical traction. He stated that we seemed to be within measurable distance of applying electric traction to tramways, and when that time arrived the company were ready to assist in the cost of substitution.

Telephony for Cavalry.—A course of instruction in telegraphy for the Austro-Hungarian cavalry has been approved by the Emperor. The object is to train commissioned and non-commissioned officers of that arm of the service for the despatch of communications by telegraph and telephone. The technical part of the course will be under the control of the chief of the Telegraph Department, who will be assisted by a cavalry officer and

Digitized by Google

three non-commissioned officers, as well as by a couple of men from the Railway and Telegraph Corps and a number of subordinate teachers.

Prevention of Gas Explosions.—Mr. W. Harpur, the borough engineer of Cardiff, writes that no trouble has been experienced in regard to the accumulation of gas in connection with the underground electric light mains, and that none is anticipated. The transformer-chambers are ventilated by running a ventilating-pipe up the side of the nearest building, and, to the best of his knowledge, this method is satisfactory. It is an open question amongst engineers as to the most practical method of preventing explosions. The culverts are drained by being provided with open bottoms to the connecting and drawing-in boxes.

Electric Traction in Italy.—A scheme has been presented to the Italian Minister of Public Works with a view to the granting of a concession to Mr. L. Besozzi, of Milan, for the construction of an electric tramway from Gravellona to Intra. The duration of the concession is suggested at 90 years, and a subsidy of £120 per kilometre of line is requested for 70 years. The total length of the projected line is nearly eight miles, and the estimated cost of construction and equipment is £60,000. According to a Berlin paper, Messrs. Schuckert and Co., of Nuremburg, are acquiring an interest in the Turin Horse Tramway Company with a view to introducing electric traction on the line.

New Central Station in Paris.—It appears from *L'Energie Electrique* that the new board of management which has been elected for the Compagnie Parisienne d'Air Comprimé has commenced the erection of a new central station on the Quai Jemmapes. The site, which is on the canal bank, will allow of the accommodation of plant to the extent of 20,000 h.p. At the present time three units of 75 kilowatts are being installed. Each set comprises a Corliss vertical engine, coupled direct to a dynamo made by the Société Alsacienne de Constructions Mecaniques. The engine-room is on the ground floor, and the boiler-house on the first floor. The boilers are of the Belleville type, four of which will be provided for each unit. The method of distribution will remain on the five-wire system as hitherto.

Synchronous Alternating-Current Motors.—The subject of transmitting energy by means of synchronous alternating-current machines was discussed by M. R. V. Picou before a recent meeting of the Société Internationale des Electriciens. The author, who stated that no special treatise existed on the application of alternating-current motors, said that in England Mr. Mordey had published the result of some investigations dealing with synchronous motors, as had also Prof. Silvanus Thompson and Mr. G. Kapp. In France, M. Blondel had issued a pamphlet on the coupling of alternators, but the author stated that it was not so simple as the method he exhibited. M. Picou then demonstrated that synchronous machines, when the excitation was once well regulated, ought to ensure the current at all loads.

Government Telegraph Works.—The Postmaster-General, accompanied by Mr. Walpole and Mr. Lamb, visited the telegraph factories at Holloway and Mount Pleasant on Saturday morning, and announced that the hours of work would be reduced to eight a day on and from March 1. He explained in general terms the conditions under which the change would be effected, and expressed his conviction that the workmen would do their utmost to make the experiment a success. The announcement was well received at both factories, and hearty cheers were given when the Postmaster-General concluded his remarks. Mr. Walpole added a few words, to assure the men that the concession which the Postmaster-General had announced on behalf of the Government was warmly supported by the responsible permanent officials, who expected that the result would be such as to afford a complete justification of the policy of the Government.

Copper Wires for Plain Leads and Cables.—The well-known firm of Messrs. Lazare Weiller and Co., who have electrolytic smelting works at Angoulême, have just issued, through their British representative (Mr. Fernand Espir, of 3, East India-avenue, London, E.C.) a pamphlet dealing with the uses of the electrical conductors made by them. The pure high-conductivity copper made by the company is produced in rods and bars for wire-rolling, and in rolled rods for wire-drawing and also for dynamos. Apart from this, the company manufacture plain leads for telephone wires, electric lighting, and the transmission of power, the conductors being made to suit any requirements in the directions of wires of all sizes, in plain cables of different sections, and in plain strips, trolley wires, etc. The pamphlet gives a lot of useful information concerning the diameters, areas, weights, and resistances of copper and silicious bronze wires and cables, and various conversion tables.

Utilisation of the Nile.—A paper was read recently before the Egyptian Institute in Cairo by Mr. Prompt, inspector-general of the roads and bridges, dealing with the utilisation of the water power of the cataracts for improving the condition of agriculture in the country. Reassured by the Lauffen-Frankfort experiments, the author suggested the establishment on the Nile near Assouan of an artificial fall of 15 metres, which, on the one hand, would allow of the storage of 500 million cubic metres of water, and, on the other, would yield 40,000 h.p. A second dam would be provided near Cairo. Mr. Prompt estimated that motive power could be supplied cheaply, that the cost of the works would amount to £1,600,000, and that the net revenue would reach 40 per cent. on the capital expended. In conclusion, the author laid stress upon the practical results which would follow the carrying out of the project, as, for instance, the irrigation of land where corn and sugar canes are grown, and the increase in the price of cotton by the use in the country of half of the total production.

Royal Meteorological Society. — The monthly meeting was held on Wednesday, Mr. R. Inwards, F.R.A.S., president, in the chair. Mr. W. Marriott gave an account of the thunderstorm and squall which burst over London so suddenly on the morning of January 23. It appears that this storm passed across England in a south-easterly direction at the rate of about 47 miles an hour—being over Northumberland at 4 a.m., and reaching the English Channel by 11 a.m. Thunder was first heard in the vicinity of Leeds, and accompanied the storm in its progress across the country. One of the most remarkable features of the storm was the sudden increase in the force of the wind, for in London it rose almost at one bound from nearly a calm to a velocity of 36 miles an hour. This sudden increase of wind caused considerable damage, and at Bramley, near Guildford, 28 trees were blown down along a track 1,860 yards in length. Mr. E. Mawley presented his report on the phenological observations for 1894, and Mr. A. B. MacDowall read a paper on some gradual weather changes in certain months at Greenwich and Geneva.

Electro-Harmonic Society.—As mentioned in our last issue, a ladies' night of this society will be held this (Friday) evening in the Banquet-room at the St. James's

Digitized by Google

Hall Restaurant, Regent-street, W. The following is the programme—Part I.: instrumental selection; song, "Sleep and Remember, Beloved" (Tosti), Mr. Arthur Thompson; song, Miss Florence Bethell; pianoforte solo, Mr. Alfred E. Izard; songs (*a*) "Les Perles d'Or" (F. Thomé), (*b*) "The Daily Question" (Meyer-Helmund), Miss Mary Hay; vocal scena, "Maya" (Roeckel), Mr. T. H. Harrison; string quartette (Schubert), MM. Gatehouse, Greebe, Chaunell, and Belinski. Part II.: vocal duet, "Oh! that we Two were Maying" (Gounod), (by desire), Miss Florence Bethell and Miss Mary Hay; Arabian love song, "Medjé" (Gounod) Mr. Arthur Thompson; violin solo, "Nocturne in E flat" (Chopin-Sarasate), Mr. T. E. Gatehouse; song, Miss Florence Bethell; song, "In Passionate Surrender" (Fredk. Rosse), Mr. T. H. Harrison; 'cello solo, (*a*) "Andante," (*b*) "Mazurka" (Popper), Mr. Mirko Belinski; new song, "In Years to Come" (Madge Conroy), (accompanied by the composer), Miss Mary Hay; instrumental selection, "Loin du Bal" (Gillet).

Oxford Meeting of the British Association.—The official report of the Oxford meeting of the British Association has been issued. The volume contains the opening address of the Marquis of Salisbury and the addresses of the nine presidents of sections. Abstracts are given of many of the papers read, and some are mentioned by title only. On the other hand, there are papers that were ordered by the General Committee to be printed *in extenso*. The latter include those on a lecture-room experiment to illustrate Fresnel's diffraction theory and Babinet's principle, by Prof. A. Cornu; the connection between chemical combination and the discharge of electricity through gases, by Prof. J. J. Thomson, professor of Experimental Physics, Cambridge; on the electrification of molecules and chemical change, by Mr. H. Brereton Baker; and a report on planimeters, by Prof. O. Henrici. The reports presented by previously appointed committees and investigators include the following: reports on the state of our knowledge of thermodynamics, by Mr. G. H. Bryan and Prof. Ludwig Boltzmann; report on experiments for improving the construction of practical standards for electrical measurements; and the report received by the Mechanical Science Section on methods of determining the dryness of steam.

Central Stations in France.—With reference to our note on this subject in our issue of 8th inst., the following are some of the details of the statistics of central electric light stations in France on January 1 last: There were at work, excluding Paris, 328 stations, against 301 on January 1, 1894, or an increase of 9 per cent. The total power amounts to 40,000 h.p., divided as follows: 151 stations use water power to the extent of 9,650 h.p. (24·5 per cent.); 39 stations water and steam power, 6,000 h.p. (15 per cent.); 119 stations steam power, 22,000 h.p. (56 per cent.); five stations poor gas, 220 h.p. (·55 per cent.); and 14 stations town gas, 1,550 h.p. (3·95 per cent.). With respect to the nature of the systems, there are 260 stations, of a total of 27,895 h.p. (70·75 per cent.), using continuous current; 73 stations, with 10,645 h.p. (27 per cent.), using single alternating current; and three stations, with 880 h.p. (2·25 per cent.), using polyphase currents. These statistics show the development of alternating stations, the average power of which is largely above that of the continuous-current stations. The average horse-power of the former is 145 h.p., and of the latter 110 h.p. Of these stations, 29 are run by municipalities. These are all small concerns utilising water power obtained cheaply from neighbouring streams. There are 26 stations, some important, exploited by gas companies. On January 1 there were 34 stations being built, and 74 were more or less advanced in project form—a total of 108 as compared with 115 at the same period last year.

The Projected Elevated Railway in Berlin.—It would appear from a report published by a Berlin newspaper that the long-projected elevated electric railway for Berlin is assuming a definite shape; but as this rumour has so frequently been spread about, it is well not to place too much reliance upon it at the moment. At the same time it may be mentioned, on the authority of that paper, that the negotiations entered into by Messrs. Siemens and Halske, the promoters of the enterprise, have been brought to a conclusion. The agreement between this firm and the municipal authorities has been drawn up and is on the point of being signed, and the negotiations for the crossing over of several existing railway lines have been concluded. The continuation of the line from the Nollendorfplatz through the Charlottenburg district to the Zoological Gardens has been satisfactorily arranged, so that the agreement between the firm and the town of Charlottenburg can now be determined. As the line from the Warsaw Bridge to the Nollendorfplatz with two branches to the Potsdam place was sanctioned by ministerial order in 1893, the imparting of the concession is now only a matter of form to be fulfilled. According to the present scheme, the elevated electric railway will commence at the Warsaw Bridge, near the Berlin Metropolitan Railway, and will terminate at the Nollendorfplatz; whilst the proposed extension of the line will be continued to the Zoological Gardens.

Municipalisation of Telephony.—Mr. Foster has asked the Chancellor of the Exchequer whether, in view of the dissatisfaction which existed in various municipal bodies, both in England and Scotland, respecting the terms of the proposed contract between the Postmaster-General and the telephone companies, and the desire expressed in the House that the matter should be properly discussed in the House before the agreement was signed, the Government would afford facilities for that purpose before the signature of the agreement. The Chancellor of the Exchequer said negotiations were already in progress which he hoped would result in favourable terms being arrived at. Captain Bagot asked the Postmaster-General in the House of Commons on Friday whether he would place upon the table of the House returns showing the earnings of the different telephone trunk wires for the past three years which he proposed to buy from the telephone companies, the price he intended to pay for them, and copies of the reports of the Post Office experts on their condition and value. Mr. Benn also asked whether the signing of the agreement could not be postponed until the question of the municipalities obtaining licenses was discussed in the House. Mr. A. Morley said that the valuation of the trunk wires of the telephone companies, which is now being proceeded with, would take some time to complete. He was therefore not in a position to furnish the information on this point. He had no accurate information with respect to the earnings of those wires. Mr. H. S. Foster asked whether the House would have an opportunity of discussing the question before the agreement was signed. Mr. A. Morley said that members interested in the question would have an opportunity of balloting for a day to bring it forward. Mr. J. W. Benn has given notice that on March 1 he will call attention to the proposed agreement between the Post Office and the National Telephone Company, and move a resolution.

Electric Motors in a Sugar Factory.—Dr. O. Köhler, in the *Deutsche Zuckerindustrie*, gives an account of an electric installation in the Groningen sugar factory. The chief plant, about half-a-mile distant from the works,

Digitized by Google

consists of two Siemens and Halske dynamos of 41,600 watts and 23,000 watts respectively, these being driven by turbines. In the factory there are, in addition to a 120-cell battery of accumulators of 594 ampere-hours, two independent steam-engines connected with two Siemens and Halske dynamos as a reserve. The dynamos supply current for 750 incandescent lamps and 10 arc lamps, as well as for five small electric motors and two large electric motors. The small motors have taken the place of steam-engines and long shafting, and have worked faultlessly for two years, and even the commutators are uninjured, as carbon brushes have been used. The economy in the employment of the motors has been specially noticeable in the case of a lift, which was formerly driven by a 3-h.p. steam-engine. The figures show that only half the amount of power is now expended. Often during the sugar campaign power is required in exceptional positions, when the conductors can be quickly run and attached to a portable motor which supplies the required power, which otherwise could only have been obtained with much difficulty and at great expense. For sugarworks, with their intermittent working and having a varying amount of product in different seasons, such a system possesses very special advantages, and Dr. Köhler is of opinion that soon electric motors will drive small steam-engines out of sugarworks, and so allow of a centralisation of the steam power. They will also obviate the use of lengthy shafting, and thus obviate waste of power. Electric motors are also specially adapted for driving centrifugal machines, when each centrifugal can be driven independently.

Electric Lighting in Germany.—Old rolling mills which were established at the beginning of the century at Dahlhausen-on-the-Ruhr, and which are now in a half-ruinous condition, are to be converted into a central electric light station. Water power is available.—An extension has taken place of the electric light installation at the central railway station, Munich, the latest portion being the lighting of the section from the engine-house to the Ullmann Bridge. The high-tension conductors are provided with catching-nets, so that in the event of a breakage the conductor would not cross other wires.—The Rendsburg Municipality propose to establish a central electricity station, and a committee has been appointed to visit other towns where central stations exist.—At Tübingen a scheme is on foot for utilising the power of the Neckar for the generation of current for lighting and power purposes.—A central station has been completed at Horb, the work having been carried out by Mr. W. Reisser, of Stuttgart. There are at present 600 lamps connected, but the local authorities having seen the excellent results obtained, have now determined to light the streets and all the public buildings electrically. The pumps of the high-pressure water supply are also to be worked by electric motors instead of by steam-engines.—The mains of the Berlin electricity works are to be extended in the western, south-western, and eastern parts of the city, and the plant will be increased by two steam dynamos of 2,000 h.p. respectively. It is intended to increase the capital of the company to £180,000.—A central station, to be erected at Gelsenkirchen by Messrs. Siemens and Halske, will supply current not only for general lighting and power purposes, but also for electric tramway lines.—The large oilworks of Messrs. von Schayck at Strälen have had the electric light installed, there being 75 incandescent lamps and four arc lamps.—The local authorities of Augsburg have invited Messrs. Schuckert and Co. of Nuremburg, and Messrs. Siemens and Halske, of Berlin, to draw up plans for the erection of a central electric light station.—By arrangement between the Bavarian Vereinsbank, the Allgemeine Elektricitäts-Gesellschaft, and Mr. Oscar von Miller, a central station is to be provided for Schwandorf. This will be the first town in the Upper Palatinate to be lighted electrically throughout.

Spectrum of the Electric Discharge.—Messrs. G. D. Liveing and J. Dewar in the *Philosophical Magazine*, dealing with the question of the spectrum of the electric discharge in liquid oxygen, air, and nitrogen, state that these, like non-electrolysable compound liquids, offer great resistance to the passage of an electric discharge, so that the spark could only be made to pass through a thickness of 1mm. of liquid. When the thickness was less than this, a succession of sparks could be maintained; but the resistance appeared to be very great, and the disruptive effect on the platinum electrodes was sufficient to discolour the liquid by the particles thrown off their surfaces. The discharge through the liquid in all cases gave a continuous spectrum and some bright lines traceable to the electrodes, whilst the rays supposed to have been emitted by the molecules of the liquid were less conspicuous. It seems not unlikely, therefore, that the continuous spectrum was due to the particles thrown off the electrodes. With liquid oxygen boiling at atmospheric pressure, and both electrodes being immersed in the liquid at a distance of 1mm. or less, a continuous spectrum is obtained, brightest in the yellowish-green, but extending to some distance both on the red and on the blue side. The absorption bands of oxygen were conspicuous on this bright background. With a Leyden jar in circuit, the brilliance of the spectrum is increased and some additional lines brought out. Many more bright lines were produced by keeping only the lower electrode immersed in the liquid, so that the spark passes partly through the liquid and partly through the gas immediately above it. Most of these correspond with known lines of oxygen. Exhaustion of the gas above the liquid, until the pressure was reduced to about 10mm. of mercury, did not make any marked difference in the appearance of the spectrum so long as both electrodes were immersed in the liquid. But when the lower electrode only was immersed and a Leyden jar put in circuit, a good many bright lines came out. The passage of the discharge through the liquid produced much ozone. Not only was the smell of ozone very strong, but the liquid took the indigo tint, deeper than the blue of ordinary oxygen, which is characteristic of ozone. The effects of the discharge through liquid air were very similar to those produced with liquid oxygen, as long as the pressure was that of the atmosphere, and no jar was in circuit. When a jar was used a much larger number of lines, generally resembling the ordinary air lines, was seen but not measured. When the pressure was reduced, the usual banded spectrum of nitrogen was seen, and was strong relatively to the spectrum of oxygen. As the liquid evaporated, and thereby lost more nitrogen than oxygen, the two green bands due to oxygen appeared to become stronger actually, as well as relatively to the nitrogen bands. In this case, the discharge produced oxides of nitrogen, which were detected in the residual gas when the air had all evaporated. With liquid nitrogen at atmospheric pressure, both electrodes immersed, a faint very diffuse line was observed at about $\lambda 501$. This became more distinct when only one electrode was immersed, and probably represents the strong double line of nitrogen in that position. With the jar in circuit the spectrum was a series of bright lines similar to those given by gaseous nitrogen at atmospheric pressure. Under reduced pressure, one or both electrodes being immersed, and no jar used, the band spectrum of nitrogen appeared. On putting on the jar, this was replaced mainly by the line spectrum.

ELECTRIC MOTORS FOR OPERATING MACHINE TOOLS AND OTHER APPLIANCES.

The question of satisfactorily employing electric motors for workshop and factory purposes does not fortunately depend upon the classical utterances of learned professors in their respective lecture theatres, nor yet upon the prejudices of engineers who consider that old-time methods are the best for modern requirements. The greatest proof of economical development in working, and of real success in this direction, is given rather by the frequency with which the erection and equipment of electric motive-power transmission plants are chronicled in the technical papers: and object lessons, such as those of the Royal Belgian Small-Arms Factory at Herstal, or the almost equally important private installations at the works in this country of Messrs. Siemens Bros., W. T. Henley's, or the Electric Construction Company, do far more good in showing the advantages of electric motors for power purposes than any amount of talk or criticism.

There is, however, some considerable degree of useful service accomplished by recording what has been done

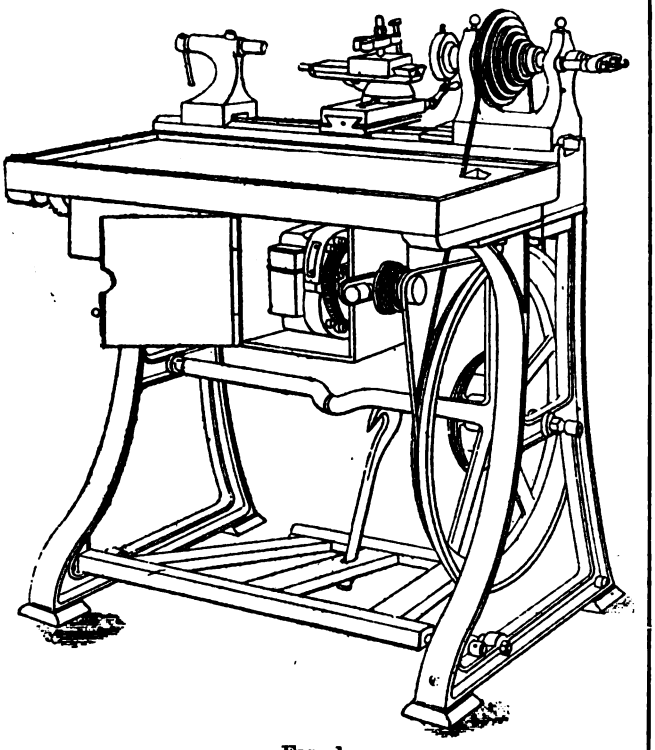

FIG. 1.

with regard to the installation of electric motors: and hence we abstract a few particulars respecting some points of interest in workshop practice from a very long exhaustive report prepared by Messrs. G. Dumont, G. Baignères, and A. Lencauchez upon the subject of electric energy transmission in general, and recently submitted by them to the Société des Ingénieurs Civils of France.

The two instances of power transmission which we have selected to place before our readers are shown in the annexed illustrations. The first of these illustrates a small foot lathe for brass or wood work. The motor, as will be seen, occupies a small box fixed underneath the bed of the lathe, and has a projecting spindle upon which is mounted a small grooved speed cone. A band from this may be connected either to the flywheel on the crankshaft or to the lathe head cone itself, thus giving a considerable range of speed. The treadle may, if desired, be kept in order to help in stopping the motion, the workman using it as a brake.

The second illustration shows the general plan or scheme of an overhead travelling crane, in which a separate motor is employed for each distinct operation, whether longitudinal or cross traverse, lift or slew. Usually these different operations are carried out by a single motor of large size, with friction-clutch devices for throwing in the spindles and gear designed for each movement. The adoption of separate motors does not, however, preclude their proper management or operation from one single point, whilst it does secure the positive advantage of greater variations in speed.

In the method illustrated four motors are used; these are all shunt wound, and run in either direction as desired. Four switch levers, connected to the machines, are mounted on a switchboard, which also carries the omnibus bars from the generator, the safety cut-outs, measuring instruments, etc. Five circuits are joined up to the bus bars; four of these pass to the motor armatures, and the fifth is the common exciting circuit used for the motor fields. Ammeters are mounted at a_1, a_2, a_3, a_4 for each circuit; V is a voltmeter, thrown in or out by a button switch, i; A is a large ammeter on the main generator circuit; I is a multiple switch whose contacts are so arranged that the current from the generator passes first through the motor fields—the armatures are then switched in by moving the switch handle further round; F is a main cut-out; f^s a smaller one in the exciting circuit;

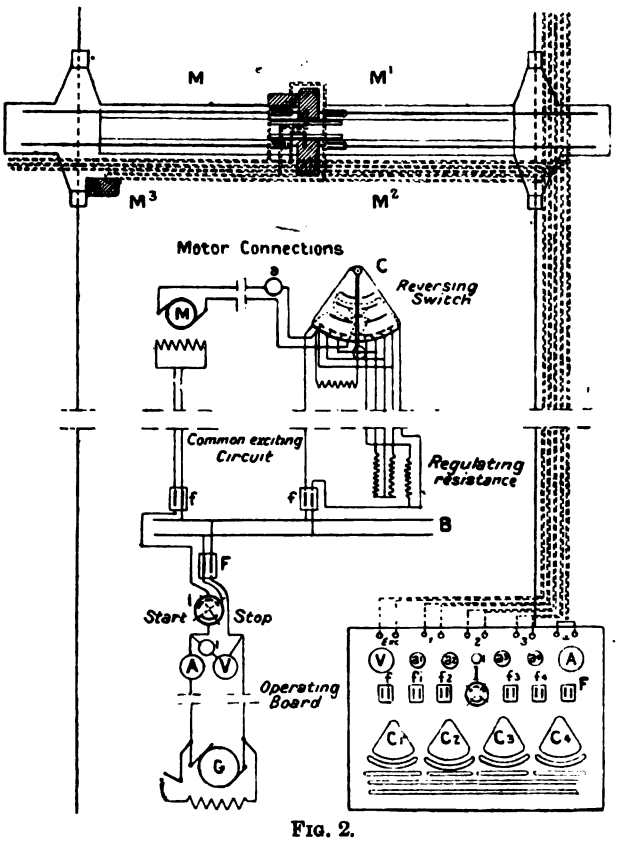

FIG. 2.

f_1, f_2, f_3, and f_4 are similar fuses in the motor armature circuits, C_1, C_2, C_3, C_4, shown at the base of the operating board, are the manual lever switches used for each motor—*i.e.*, each desired operation: traverse lengthways or across, lifting, and swivelling. When the lever of any switch is in a vertical position (as may be seen from the inner diagram, which represents the connections of one motor) the armature of that machine is short-circuited through a resistance of sufficient amount to avoid excess of current; throwing the load off in this way through a powerful resistance acts as a brake, and gives considerable ease of manipulation.

By turning the lever to right or left, the armature is switched in through a regulating resistance, which is either partly or wholly switched out as the handle moves along the contacts to its extreme points on the right or left. Three different speeds may thus be obtained whether running backwards or forwards, the limits being:

	Empty.		Full load.
Cross traverse.....	150ft. per min.	...	75ft. per min.
Longitudinal traverse	75ft. ,,	...	36ft. ,,
Lift	13ft. ,,	...	5ft. ,,

for weights of from 15 to 30 tons. The regulating resistance may, of course, be calculated so as to give any

Digitized by Google

desirable ratio of speed at the different positions of the switch lever.

M, M^1, M^2, M^3 represent the four motors respectively of 6, 10, 10, and 6 h.p. The method of operation is very simple, and does not need elaborating here. A somewhat novel point is the use of the multiple switch, I, which offers the advantage of maintaining the motor fields when momentary stops are made by cutting out their armatures. Of course, by turning the handle of I further round, the exciting current is also cut off, and the motors thus isolated from the generator.

THE DISABILITIES OF YOUTH.

BY THE PHILOSOPHER.

The very characteristic inaugural address of the new President of the Institution of Electrical Engineers is probably still fresh in the minds of most engineers—at any rate, of most electrical engineers. I do not here propose to deal with the whole of that dissertation, but I would examine carefully one not insignificant portion.

I refer to the "note of warning" that was sounded ostensibly for the special edification and enlightenment (?) of town councillors, who were advised to beware of employing young engineers in the preparation and subsequent execution of their electric lighting schemes. Now, I think that most fair-minded folk will agree that before making a statement of this sort—an announcement that may, and probably will, damage the immediate prospects of more than one career honourably begun—Mr. Crompton should have satisfied himself that there really existed a need for this peculiar gratuitous supplication to British town councillors, a class of persons who, though usually ignorant of electrical matters, are nevertheless, for the most part, men who have no small fund of common sense and shrewd business acumen. But we have it on the authority of Mr. Raworth, a gentleman whose special knowledge of this particular subject probably exceeds Mr. Crompton's, that the young electrical engineers whose services have been requisitioned by provincial corporations have, on the whole, done good work, have given good advice, and have, in a word, so conducted themselves as to do credit to themselves and to the Institution to which most, if not all, of them belong.

Obviously, either Mr. Crompton or Mr. Raworth is right. To the most ordinary and casual observer of human affairs it must be abundantly clear that years alone are no criterion of a man's fitness to advise on important engineering matters. A young man almost necessarily possesses energy; he is in a position, if only he has the inclination, to profit by the experience of others who have gone before him, and he is much more likely to give free and impartial consideration to the various methods for arriving at a required result than is the older man, whose opinions have been formed and crystallised into prejudices. The young engineer knows very well that his work will be subjected to a keen criticism, to a searching examination that will not be directed towards the efforts of the man whose reputation has been made, and it may safely be asserted that this very knowledge will cause him to give an amount of careful thought and attention to his maiden effort that ought, and generally does, bring about a satisfactory consummation to his labours. If then, on general principles, it has been shown that Mr. Crompton's "warning" was unnecessary, unjust, and uncalled for, and if, further, it has been shown by Mr. Raworth that the statements which immediately followed the "warning" were inaccurate—that is to say, that our young engineers have done well, and not badly—then one is naturally inclined to a speculation as to the motives which could have prompted our President's reckless and ungenerous utterance. For my part, I can only arrive at one conclusion. It is a well-known fact that Mr. Crompton is more interested in continuous-current patents and appliances than he is in advancing the claims of alternating-current apparatus. There is, perhaps, no more out-and-out advocate of direct-current methods than Mr. Crompton. It is not surprising to find that those who advocate his opinions are amongst the older consulting engineers—men whose electrical convictions were formed before the alternating current entered into the domain of practical engineering politics. Nor am I in the least astonished to find that the younger generation of consulting and executive electrical engineers are the staunchest advocates of alternating current for town-lighting, because they see in it the only simple and ultimate method of economically serving large and increasing areas. What, then, is the result of the above considerations? Simply that Mr. Crompton is very human, simply that he wishes his company to prosper, simply that he knows this is most likely to happen if town-lighting be carried out in accordance with the views and to the specifications of the "older generation" of electrical engineers. It is sheer affectation to pretend that any of us are not self-interested. But some of us occasionally display a little regard for the material well-being of others. So much we have a right to expect from the President of the Institution of Electrical Engineers.

THE INCANDESCENT LAMP.*

BY MANNING K. EYRE.

(Concluded from page 160.)

Enough has been said to show the absolute necessity of a good vacuum, or at least as perfect as we can make it, so we can at once proceed to the description of the process of exhaustion. Fig. 5 is a rough sketch of one of the aisles in the pump-room. In the sketch, *f*, are two large pipes, the upper one feeding the mercury to the pumps, the lower one carrying it off to the reservoir. The mercury is kept in circulation by means of a rotatory screw pump, keeping the Sprengel pumps fed as long as there is a demand

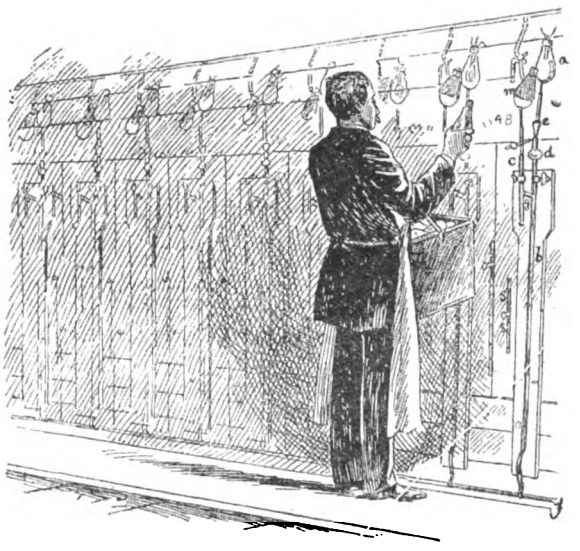

FIG. 5.—Exhausting Lamps.

for the mercury. The lamp, *a*, after leaving the glass-room, is rubbered—that is, a small rubber cap is placed on the end of the small exhaust tube, which, when the lamp is placed on the pump, fits into the cup, *e*, forming an airtight joint. As the process for exhaustion continues, the internal pressure being removed, the external pressure forces the lamp and tube more and more into the cup, *e*, making a tighter joint where a tight joint is most necessary. Below the joint is a small receptacle, *d*, in which is kept a little phosphoric anhydride to absorb any moisture. Below this again is the main tube, *b*, through which the mercury and air fall. This tube must be a few inches longer than an ordinary barometer tube, 30in The action of the pump is very simple. The lamp having been placed on the pump, the mercury carried over in the upper pipe, *f*, falls in a fine stream through the small tube, *c*, and connecting tube, *g*, and at this point forces air down the long tube, *b*. The mercury in falling acts exactly as though it were a succession of small pistons, following each other rapidly, and each one forcing a bubble of air down and out through the long tube and circulating

* The *Electrical World* (New York).

Digitized by Google

pipe, *f*. The consequence of this is for the first few minutes that the lamp is on the pump, the column of mercury in the tube *b* is full of falling bubbles, and as the process continues the bulbs get smaller and smaller, and fewer in number, giving a very good ocular demonstration of the progress of the exhaustion. Very soon the tube will appear solid—that is, with no bubbles—indicating that no more air can be forced out under the existing circumstances. The vacuum is, however, far from complete, there still being a considerable quantity of air clinging to the glass and to the filament. In addition to this, the filament itself and the clamps contain gases which must be driven out before the vacuum is complete. Up to this point no current has been allowed to traverse the filament, the lamp being consequently cold. Resistances are placed in series with each lamp, and by means of a small plug, *s s* (Fig. 5), can be thrown in or out, regulating the amount of current passing through the filament. The lamp is now allowed to burn at a dull red for several minutes. This heats the lamp, and some of the air clinging to the glass is forced out and caught by the falling mercury. The column of mercury, which had previously become solid, now becomes filled once more with bubbles, though much smaller than before. Some of the gases are also driven out of the filament and clamps. When the bubbles have nearly ceased again the lamp is flashed, and then allowed to burn, driving more air and

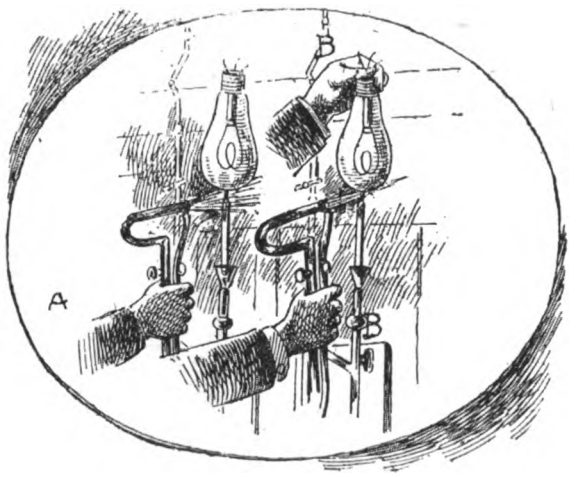

FIG. 6.—Sealing-off.

gases out. This process is repeated until the lamps are all burning at something above normal candle-power, and when the mercury tube once more appears solid and free from bubbles, the vacuum may be considered attained.

The next operation is known as "sealing off," and consists in taking the lamps off the pumps without losing the vacuum. This process is indicated in Fig. 6, the dull flame being for the purpose of gradually heating the glass, and the hot pointed flame doing the work. The operator holds the blow-pipe in the left hand, and with his right lifts the lamp off as the glass melts.

The lamp is now ready for basing, though as a rule this is not the next step which it undergoes. The natural order would at first sight seem to be to base the lamp and then to test it, but commercial considerations renders this impossible. Lamps are manufactured with so many different bases—the Edison, Thomson-Houston, Westinghouse, Mather, Hawkeye, Brush, Swan, etc.—that it would require a stock of millions of lamps to supply only a moderate demand at short notice. By carrying them in "wire-stock," however, this difficulty is overcome in a great measure, the lamps being based to order. As the method of testing, however, is the same whether the lamp is based or unbased (wire lamp), it will be best to finish the manufacture first and describe the testing after. Fig. 7 shows the various stages of socketing: 1 is the frame consisting of a long bench, perforated with circular holes, which receive the mould, 2. The mould is made in two sections to admit of the lamp being more easily removed. The Edison base consists of two parts—the button and the shell. These having been placed in the mould, the lamp is laid on the frame, as shown in Sketch 4, Fig. 7. The wires are so arranged that one is in contact with the button, the other with the outer shell. Plaster is then poured in the mould, filling the base. The lamps are then raised to a vertical position, and forced by hand into the plaster, and a small vertical hollow rod pushed down over the small projection on the end of the bulb; this serves to keep it straight and steady it while the plaster hardens (see 5, Fig. 7). The lamps are then placed in a drier, as damp plaster causes short-circuiting, moisture being a fair conductor.

The lamps are now ready for the photometer test. A great deal of mystery seems to surround this test in the minds of many people, though it is exceeding simple in principle. Nevertheless, too much care cannot be taken with this test, and it is necessary to employ the best of labour. Although I have stated that the principle is simple, I do not by any means wish to be understood to imply that a successful photometer test can be made by anyone. On the contrary, an inexperienced person would be very apt to find his readings differing by several candles when there should be, and probably is, no practical difference. The photometer is shown in Fig. 8, and consists of a long bar, to the centre of which is attached a screen, shown in 2, and is simply a rectangular frame holding a disc of paper, in the middle of which is a grease spot, A. On either side of this disc are fixed small mirrors, B B, at an angle so that an observer looking at A

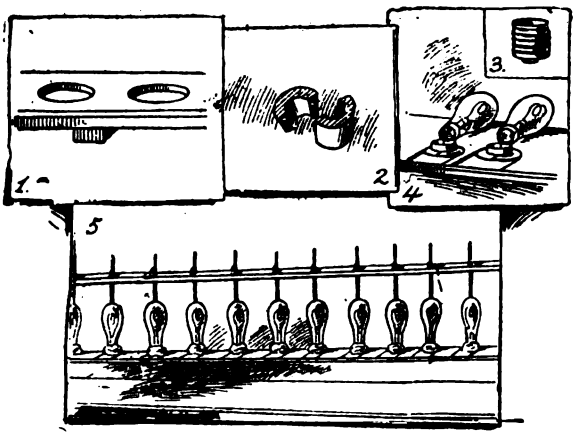

FIG. 7.—Socketing.—1. Frame.—2. Mould.—3. Shell.—4. Lamps ready for Plaster.—5. In Plaster. Hardening

on edge sees two reflections of the grease spot in the mirrors, B B. On top of the photometer is the galvanometer for keeping the voltage constant, and on the photometer bench can be seen the ammeter (under the screen) and the voltmeter, near the lamp to be tested. At the opposite end of the photometer bar is shown the standard lamp.

In many factories only a comparatively small percentage of the total product is tested on the photometer, the balance of the lamps being placed on racks with some of those tested, and sorted out by means of the eye. This method is, however, unsatisfactory, though it gives much closer results than is apt to be supposed. Much better results can be secured by testing each individual lamp, which method, though expensive, is thoroughly reliable.

The standard of candle-power varies, and is different in the United States and in Europe; and, in fact, were the same lamp sent to different laboratories throughout this country, quite a variety of results might be expected. The original standard, or unit of light, may be the flame of a candle or a portion of the flame of an Argand burner. In comparing standards with the original unit of light, the Methven screen is used, which allows only a small portion of the centre of the flame to shine on the grease spot of the photometer, this part of the flame remaining more nearly constant. In the factory, however, standard lamps of different candle-power are manufactured and kept constantly checked up, new ones being made up from time to time. In order to test a lamp, a standard lamp, say, of 16 c.p., is placed at one end of the photometer bar, the voltage of this standard being kept absolutely constant. The lamp to be tested is mounted at the other end of the

Digitized by Google

photometer, the screen and mirrors being in the middle, and equidistant from the lamps. In shunt with the lamp to be tested is a voltmeter, and in series with it an ammeter, the latter being used only where the efficiency is to be tested or when the lamp is destined for series work. One operator sits directly in front of the screen, and by moving a slider changes a resistance in series with the lamp to be tested. This alters the amount of current passing through the lamp, and consequently the amount of light given out by it. The operator at the same time is watching the reflections of the grease spot in the mirrors. As long as the intensity of light on the two sides of the spot is unequal, the reflections will be quite different in appearance—one being dark, the other light When the intensity of the lamp to be tested is exactly equal to that of the standard 16-c.p. lamp at the other end of the photometer, the images of the grease spot become exactly alike in appearance, and, in fact, almost entirely disappear. The other operator reads the voltage as indicated by the voltmeter, and the lamp is so marked. Care must be taken that the standard is mounted in its socket at the exact angle at which it was originally standardised, as the intensity of light varies with the angle which the plane of the filament presents to the photometer bar. For the sake of uniformity, all lamps are tested with the filaments in the same relative position to the photometer, otherwise it would be impossible to compare results or check the test.

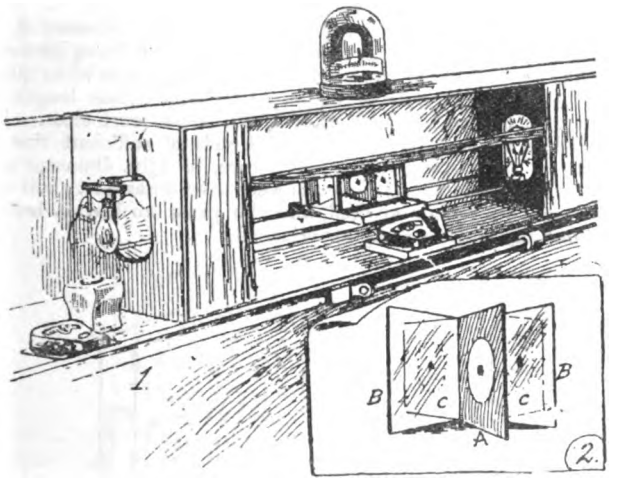

FIG. 8.—1. Photometer.—2. Disc and Mirrors.

This is so important a subject, and so many practical points are involved in it affecting the user of lamps, that I regret more space cannot be devoted to it, especially as at the present time many large consumers of lamps are fitting up photometers with the idea in view of testing the product of factories. This is undoubtedly a very sensible plan; nevertheless, there is trouble in store for all of us until the use of the photometer is thoroughly understood. At the lamp works of the General Electric Company, every lamp is tested on the photometer, and before shipment, an additional test, known as the rack test, is applied. This, briefly, consists in placing the lamps in a long horizontal rack and passing a low current through them, bringing them all to a dull red. In this position it is very easy to pick out any lamps showing defective filaments, such as spotted carbons. These are weeded out and the voltage raised until the lamps are all burning at about normal candle-power. The percentage of lamps thus weeded out is very small, because after every process in the factory expert inspection is made of the product, making about 70 inspections in all. Another source of possible error is at once detected on the rack—namely, mixing lamps of different candle-powers, caused by errors in making. It seems rather a curious fact that if two lamps, one of 16 c.p., the other of 20 c.p., but both of the same efficiency, were placed side by side, it would be extremely doubtful whether the difference would be noticed by any but the most experienced eye; on the other hand, place two 16-c.p. lamps together, of different efficiencies, and the disparity can be readily detected, though they are of the same candle-power. On the rack test nearly all errors are apt to be discovered, because since the lamps are all at the same voltage, any error appears at once at a difference in efficiency, except in the case of two lamps of the same efficiency, same voltage, and different candle-power. This is so improbable an error that its occurrence need not be considered. To explain what is meant, let us suppose two filaments, one very small and fine, giving 10 candles of light, and consuming 30 watts, or three watts per candle; the other, very large and coarse, giving 20 candles, consuming 200 watts, or 10 watts per candle. The small filament would burn very white and would apparently be giving much more light than the coarse filament, which would burn very dull. The surface of the latter filament being so much greater, it is really giving out twice as much light. The lamps which are not kept barrelled up are carried in the factory in racks each containing a certain number of lamps, and are of great assistance in counting. A miscount in shipment is very rare. The lamps have now only to be cleaned, labelled, and wrapped, and they are ready for barrelling up.

It is sometimes disheartening, after all the care taken in the manufacture of the lamps, to hear the complaints made by owners of plants, which in nine cases out of ten (and this is not in the least an exaggeration) are due to some misuse of the lamps. To begin with, a lamp should be fitted to a plant's pressure, just as much as a shoe to give satisfaction should be fitted to a man's foot, and after the

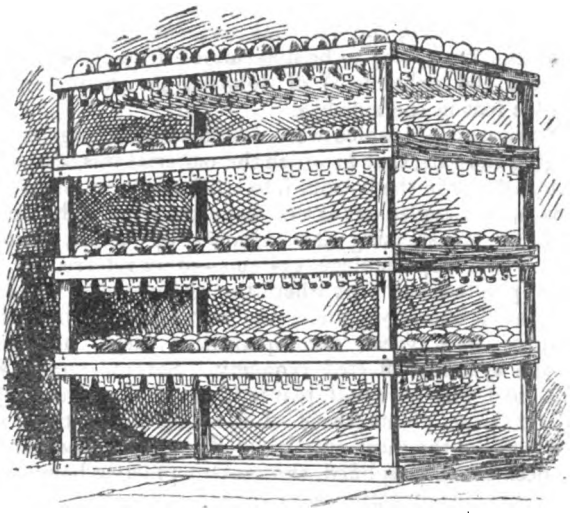

FIG. 9.—Lamps in Rack ready for Barrelling.

lamp is so adjusted to the requirements, the regulation should be kept constant. In no other way can lamps, no matter of what manufacture, give satisfaction. Good regulation means running the plant within one volt either side of the marked voltage of the lamps. This can be appreciated when it is understood that to run a lamp four volts above its voltage shortens its life to exactly one-half; eight volts high reduces the life to one-quarter. In other words, a 100-volt lamp whose normal life is 1,000 hours, if burned at 104 volts will live 500 hours, and if subjected to 108 volts will only burn 250 hours. I have tested plants supposed to be running at 104 volts, which showed on test to be really 120 volts. Imagine the effect on the lamps! It is not at all an uncommon thing for plants to vary the regulation 10 or 15 volts; in fact, the only uncommon thing in the business is to find good regulation outside of the very large illuminating companies, and even there it is by no means perfect. It being the season of the year when good resolutions are in order, let us resolve "to keep our regulation perfect."

THE EXTRACTION OF GOLD BY THE CYANIDE PROCESS.

A paper on this subject was read on Tuesday before the Institution of Civil Engineers by Messrs. Charles Butters and Edgar Smart, A.M.I.C.E., Sir Douglas Fox, vice-president, being in the chair.

The "cyanide" process of extracting gold from ores and tailings, in which the gold, after being dissolved by

Digitized by Google

cyanide of potassium, was precipitated from the solution by zinc shavings or electricity, was first briefly described. For plant to carry the process into effect, it was shown that the best site was one having a fairly steep and uniform slope downwards from the material to be treated, for this not only allowed the lip of the treatment vats to be placed below the level of the tailings, which might therefore be run into them by gravity, but also gave plenty of space below the works for dumping the residues after treatment. Typical examples were described and illustrated of works built upon convenient and inconvenient sites. The size and number of vats were stated to depend not only upon the quantity of material to be treated in a given time, but also on the time occupied in filling and discharging the vats and in leaching. The zinc process occupied a period of between 60 and 84 hours, so that with the time for the filling and discharging a complete cycle of operations was performed in just four days and night. A longer period of 110 hours was required for the Siemens-Halske electrical process on account of the weak solution of the cyanide with which it could be worked. A larger size for the vats than 600 tons capacity was not recommended by the authors, but up to that limit they had found a few large vats to be more convenient than a large number of small ones. For a plant with five vats, each of 600 tons capacity, the sizes of the alkaline-wash, strong-solution, and weak-solution tanks were given as 300 tons, 300 tons, and 450 tons respectively. The capacity of the zinc-boxes was to be determined from the rule that each ton (26 cubic feet) of solution per hour required 21 cubic feet in the zinc-box.

Of the methods which were described of filling and discharging the vats, that in which the material was discharged through doors in the bottom into trucks running in a tunnel beneath, was singled out as that to be preferred. The various means of transporting the tailings—by mules, hauling-engines and rope-haulage systems—were referred to, and it was pointed out that where the tailings were scattered the use of hauling-engines was advantageous, but where distances were great and quantities large, mechanical haulage systems effected economy. Several pumps were mentioned, but for small plants those of the donkey type, and for large plants those of the centrifugal type, were described as the most suitable. The piping arrangements had been much simplified, the present practice being to use one large pipe connecting, with separate cocks, all the solution tanks to all the leaching-tanks, through a centrifugal pump, when necessary. Iron plug cocks were stated to be unsuitable for the work on account of the film of oil being dissolved by the caustic potash which resulted from the process, and packed case valve was referred to as the only type which could be used with safety. Suitable sizes for the charging and leaching pipes for different diameters of vats were given.

The usual method of collecting sand and slimes by means of "tailing dams" was described, and its results upon their distribution and character in regard to future treatment were considered. It was demonstrated how it was possible, and of common occurrence, for slime lumps to assay higher after treatment than before it, on account of their absorbing the solution which had dissolved gold from the sand and retaining it occluded in their masses. Methods of ploughing, harrowing, and shovelling were mentioned for reducing the dry slimes to fine powder, and various forms of disintegrating machines for the same purpose were described, and the advantage was emphasised of dealing with the tailings directly they leave the battery. Particulars were given of the system worked out by the authors in conjunction with Captain Mein, in which collecting-vats, having filters and bottom discharge doors, the water running off over the whole periphery of the vat into a trough which conducted it to the slime pits, were used. The best form of distributor was described, and the sizes for the vats which had been found most effective in practice were tabulated. Brief mention was then made of some trial methods for shine treatment. Descriptions followed of four works which had been chosen as typical examples of the application of the plant to the varying conditions found in each case.

The Main Reef Cyanide Works, designed to treat 7,000 tons of tailings per month by the zinc process, and built in April, 1893, was first described, and particulars were here given of the method of construction and materials of the vats and zinc-boxes. The Princess and the Simmer and Jack Cyanide Works of 3,000 and 15,000 tons per month capacity, respectively, both using the zinc process, were next dealt with; and with reference to the latter, in which were the largest wooden leaching-tanks on the Witwatersrand goldfields, further particulars were furnished of the construction of the tanks, discharge doors, and furnaces for roasting the slimes. The process of cleaning up the gold by the zinc precipitation process was also described. The paper concluded with an account of the Worcester Cyanide Works, at which the Siemens-Halske electrical extraction process was in operation, details being given of the electrical boxes and of the method of the recovery of the gold from them.

THE APPLICATION OF THE ELECTRIC ARC SYSTEM OF WELDING TO MACHINERY AND BOILER REPAIRS.*

BY HENRY FOSTER.

(Concluded from page 198.)

Fig. 8 represents in detail the drawback piston and piston-rod of a Davy 2,000 tons hydraulic forging press. When working it was found that the drawback piston-rod, *a b*, was 10in. too long at end *b* to admit of forgemen's cutters, etc., being readily used, and as the swelled portion of piston-rod at end *b* was only 9¼in. long, it did not admit of being screwed further up and at the same time suit existing nuts when 10in. had been cut off ends of piston-rods. The excess length of 10in. was, however, cut off, after which bosses were electrically welded on to the 4¼in. diameter shaft ends of sufficient size to admit of their being turned, as before, to 4¾in. diameter and 9¼in. long. The piston-rod ends were then screwed to suit old nuts and afterwards erected, and the press worked as before without any trouble being experienced.

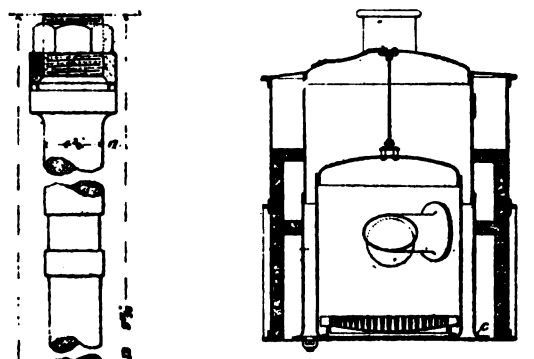

FIG. 9.

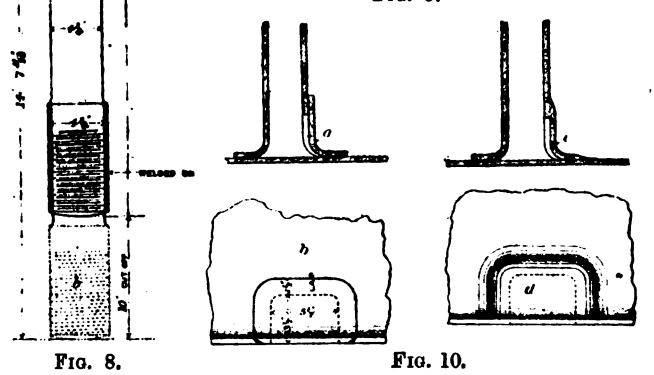

FIG. 8. FIG. 10.

Apart from the general work done at Newburn by this process in the repair of slightly defective steel castings, many other instances might be cited where repairs of a similar nature to those already described have been done; such, for instance, as welding in the teeth of cast-steel wheels which have been broken out while working, without removing the wheels from their shafts; but one more example must suffice before proceeding to treat of the application of the process to boiler repairs.

STEAM-BOILER REPAIRS.

The first application of the process of electric arc welding in connection with steam-boiler repairs at Newburn was made in September, 1891, upon a boiler supplied by Messrs. Joseph

* Paper read before the North-East Coast Institution of Engineers and Shipbuilders.

Digitized by Google

Booth and Bros., Rodley, near Leeds, for driving one of their 35-ton overhead steam-cranes, and shown in sectional elevation by Fig. 9. This boiler, which is eminently adapted for raising a large volume of steam in a limited space, is provided with an outer casing lined with firebrick, built in the form of flues, which completely encircle the outer shell of the boiler, so that the hot gases from the fire are compelled to pass entirely round and in contact with the outer shell before escaping at the chimney.

The defect, which was situated at *c*, Fig. 9, where the outer shell of boiler is riveted to bottom plate, had originally existed as a leak, which, not being visible from the outside, had caused considerable corrosion at this point before it was discovered, and when the corroded parts had been cut away to full plate thickness, a hole was left in the outer shell, 5½in. long by 3½in. deep, and extending round the bottom flange of outer shell in the immediate vicinity—a somewhat difficult place to fix a patch without removing the internal firebox. Before commencing to electrically weld the defect, a piece of mild-steel plate was neatly bent and dressed to fit the outside of the boiler shell and bottom plate, as shown in sectional and front elevation at *a* and *b*, Fig. 10, and having 1½in. lap all round the hole. The patch plate was then laid in position over the hole, and the electric arc struck upon the junction of the patch and boiler shell, so as to melt together and thoroughly incorporate the lap of the patch with the boiler shell and bottom plate which it overlapped, and under the action of the electric arc the outer edges of the patch plate were gradually drawn away to nothing, and made to loose themselves in the boiler shell and bottom plate, as shown in sectional and front elevation at *c* and *d*, Fig. 10. The internal firebox was not removed or otherwise disturbed to facilitate the work, and after being welded, the boiler was tested under hydraulic pressure to 140lb. per square inch and found perfectly tight, the whole operation of fitting the plate, welding, and testing the boiler only occupying 10 hours. Since being electrically welded, now nearly 3½

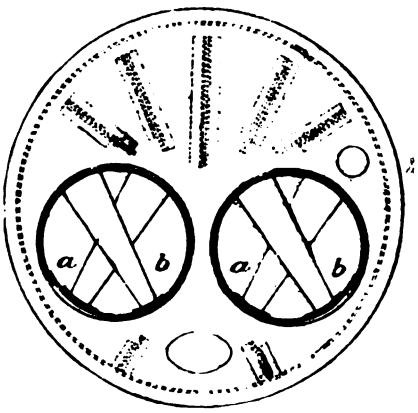

FIG. 11.

years ago, this boiler has been in constant use at the original stipulated steam pressure of 70lb. per square inch for six days per week, without showing the slightest indication of fatigue.

Fig. 11 is an end elevation of Lancashire boiler 28ft. long by 7ft. 6in. diameter. Four of these, numbered respectively 5, 6, 7, and 8, owing to defective construction of flues and furnaces, have given considerable trouble in working. In these boilers (which were constructed for a working pressure of 100lb. per square inch) the different lengths of flue, instead of being welded and made truly cylindrical, are each formed with single riveted lap joints below firebar level, and the alternate lengths made to break joint at *a* and *b*, Fig. 11, and joined together by Bowling hoops as shown. Where the lap joints of flues make joint with Bowling hoops, they are drawn to a fine edge, and with the expansion and contraction of the flues under pressure, a heavy stress is brought to bear upon the Bowling hoops in the immediate neighbourhood of the joints, with the result that the Bowling hoops crack in the corners, as shown at *a*, Fig. 12, through a certain portion of their circumference immediately opposite the longitudinal joints in the flues—the cracks in every instance being in the corner adjacent to the lap joint—and although not immediately dangerous, the working of boilers had to be discontinued owing to excessive leakage. To fit new flues, or even to fit new joint rings in place of Bowling hoops, would have necessitated the boiler fronts being taken off, which, irrespective of the expense, in this case implied that part of the working plant must stop for want of steam.

The trouble commenced with No. 8 boiler in September, 1893, and in the first instance was confined to one boiler only and one Bowling hoop, the crack being 13in. long, and extending about even distance on either side of flue joint. It was proposed to electrically weld the defect *in situ*, but before doing so the Boiler Insurance Company were requested to allow their inspector to attend and witness the process of electric arc welding as carried on in another department of the works, and satisfy himself as to the feasibility of the proposal. This being done, the boiler was electrically welded as follows: A pair of ordinary electric cables were procured, of sufficient length to reach from the electric lighting dynamo to the boiler, and of sufficient size to carry the necessary current. One end of cable No. 1 was attached to the positive terminal of the dynamo, and its other end to the boiler manway cover; while one end of cable No. 2 was attached to the negative terminal of the dynamo, and its other end to the resistances, which in this case, as in others already cited, consisted of a number of ordinary arc lamp resistance coils. From the resistance coils a flexible cable was carried over the boiler front and into the boiler flue, and terminated at the carbon-holder held by the workman. The crack was then gouged out, and welded up by inserting small nuggets of mild steel and melting them under the influence of the electric arc and gradually incorporating the new material with the old in the vicinity of the line of fracture, the form of finished weld being shown at *b*, Fig. 12, where the shaded portion indicates new material added. The welding operation occupied about five hours, and, when completed, the boiler was tested under water pressure to 150lb. per square inch, and found perfectly tight, and steam was raised in this boiler on the following day.

Exactly the same trouble as that above recorded was experienced with No. 6, 7, and 8 boilers in October, 1893, the crack in Bowling hoop of No. 8 boiler being at opposite side of flue to that previously welded. No. 6 boiler was electrically welded on Saturday, October 14, No. 7 on Sunday, October 15, and No. 8 on Monday, October 16, and, after being tested under water pressure, as before, were all working under full steam pressure at 6 a.m. on October 17. In the case of No. 8 boiler,

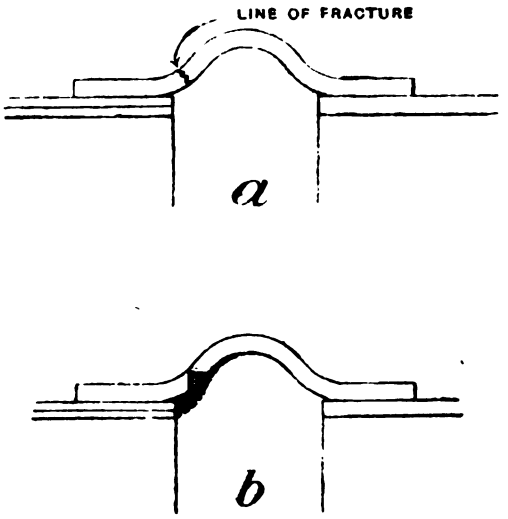

FIG. 12.

the exact time occupied in welding the crack (5in. long) was recorded as follows:

Boiler blown off at.....	1.30 p.m.
Commenced to electric weld at	3.0 ,,
Welding completed at	4.30 ,,

All the boilers continued to work almost without interruption and without trouble being experienced until August and September, 1894, when very heavy firing was necessary to meet the increased demands for steam, and it was again found necessary to electrically weld the boilers as follows:

August 11.—Electrically-welded Bowling hoop of No. 5 boiler, crack 4½in. long.

August 12.—Electrically-welded Bowling hoop of No. 6 boiler, crack 11½in. long.

September 1.—Electrically-welded Bowling hoop of No. 6 boiler, crack 3½in. long.

September 17.—Electrically-welded Bowling hoop of No. 6 boiler, crack 1½in. long.

September 17.—Electrically-welded Bowling hoop of No. 7 boiler, crack 10¾in. long (left-hand tube).

September 17.—Electrically-welded Bowling hoop of No. 7 boiler, crack 2in. long (right-hand tube).

In two or three instances cracks have again occurred through the electrically-welded joints, but this has always been directly opposite the longitudinal seams of the tubes where fracture of original hoops took place; and from experience gained in welding these defects and carefully noting their behaviour, the writer is of opinion that by electrically welding the Bowling hoop and tube together in the immediate neighbourhood of the junction of longitudinal seams with the Bowling hoops, and slightly increasing the total thickness at this part by building up and thereby stiffening the joint, the trouble can be entirely overcome, if this has not already been done, seeing that it has

Digitized by Google

not been again necessary to weld the joints since September, 1894.

Cutting and Boring.

Another very simple application of the electric arc is that of cutting and boring metals roughly to shape, and in work of this kind the same methods of procedure apply as in all the other cases cited—viz., that the article to be cut is made to form one pole, and the carbon pencil the other pole. Under these conditions, if the carbon pencil is brought in contact with the metal to be operated upon, an arc is immediately struck between the carbon pencil and that part of the metal in contact with it at the time, with the result that the metal is instantly melted in the immediate vicinity of the arc, and may be allowed to flow away as it is melted. In this way holes may be pierced in steel, iron, or other plates with great rapidity, and by moving the arc gradually along the holes may be elongated into slits of any required length or shape at the option of the workman.

Fig. 13 shows a wrought-iron tube sunk in the river bank and surrounded with broken slag and gravel. The object of this tube is to form a large strum from which water may be pumped at all states of the tide, and originally it was lying in stock as a plain tube without holes in side plates. The tube, as shown, was sent to the electric welding shop at 8 a.m., and between that time and four o'clock on the afternoon of the same day 304 holes, each about 1in. diameter, had been pierced through the 5-16in. thick side plates, the actual rate when working being between two and three holes pierced per minute.

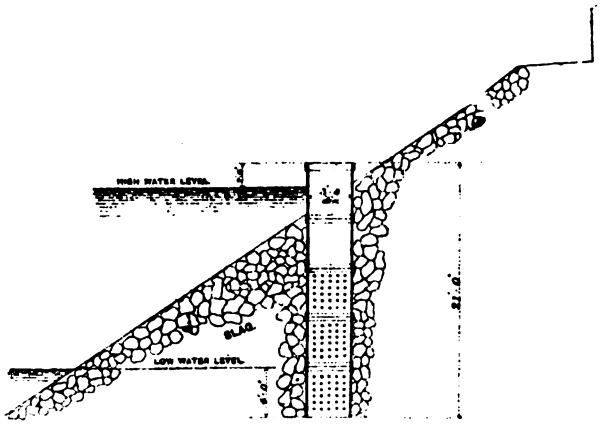

Fig. 13.

Many other illustrations of the application of the electric arc to cutting and boring *in situ* might be given, but doubtless sufficient examples have been recorded to illustrate the general utility of its application to work of a similar nature.

Plant and Apparatus Required.

The plant and apparatus necessary to effect all ordinary repairs, or to perform the operations of cutting and boring as described, may be of the simplest description, and in places where an ordinary low-tension electric arc lighting installation is in operation practically everything necessary is in stock. In any case, however, where the necessary plant has to be provided for arc or incandescent lighting, it may be arranged as follows, and made to serve the double purpose of lighting during the night, and welding, etc., during the day as desired, providing both duties are not required at one and the same time.

A combined engine and boiler of the type frequently supplied for driving dynamos in connection with electric lighting installations and equally well adapted for welding purposes, may be put down. The dynamo in this case should be of the ordinary compound-wound type, and capable of giving a continuous current of not necessarily more than 500 amperes, but certainly not less than 300 amperes, at a pressure of 65 to 95 volts, the best welding results when working on steel or iron being apparently obtained with 500 amperes at 80 volts pressure. The cable attached to the positive terminal of the dynamo should be carried without interruption, as shown by Fig. 14, direct from the dynamo to the article, *c*, required to be welded or otherwise operated upon, and electrical connection made by attaching the uncovered end of cable to the iron table on which the work lies, or it may be attached to the work itself. At any convenient point between the dynamo and the workman's carbon-holder, *b*, the negative cable should be divided, and resistances, *a a*, interposed as shown, except in special cases where the cables are sufficiently long to render resistances unnecessary. The resistances may be composed of a number of bars of iron, wound in the form of helical springs to reduce the space occupied, or, preferably, the resistance coils ordinarily used in connection with the arc lamps may be utilised and arranged as shown by Fig. 14, the only necessary condition being that sufficient resistance be interposed to ensure a steady continuous arc at the operator's carbon, *b*, and in all ordinary cases this will be obtained by a drop in the voltage of that portion of the negative cable lying between the resistances and the operator's carbon, as compared with that portion lying between the negative terminal of the dynamo and the resistances, of about 30 to 35 per cent.; or, in other words, if the pressure at dynamo be, say, 80 volts, the pressure at operator's carbon should be, say, 52 to 56 volts to ensure a steady and continuous working arc, and this will generally be obtained by interposing from 24 to 28 ordinary 3,000-c.p. arc lamp resistance coils, as shown at Fig. 14.

Of course, a very much more portable and equally efficient regulating resistance may be arranged, but in this case cited it is assumed that only the arc lamp resistance coils are at hand. A short portion of the cable to which the operator's carbon-holder is attached should be flexible, so as to admit of easy manipulation of the arc, and as light as possible consistent with

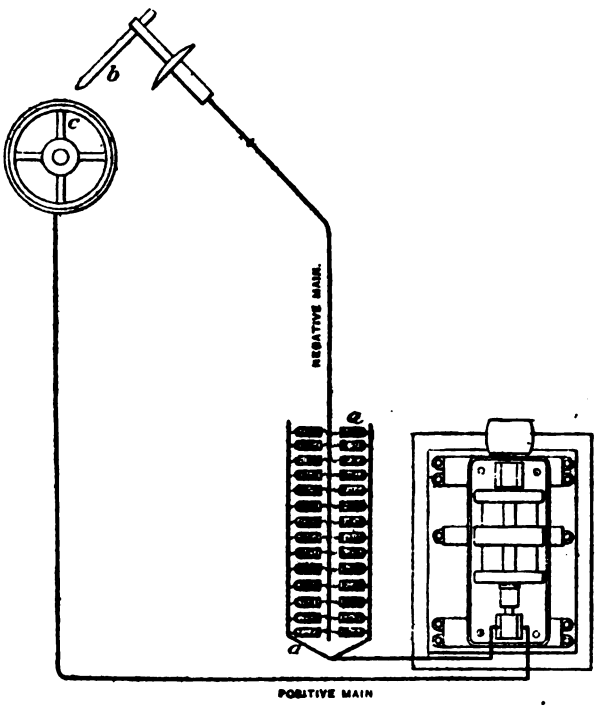

Fig. 14.

its carrying the necessary current without undue heating. The face and eyes of the workman must in all cases be protected, that portion of the protector covering the eyes being of coloured glass, preferably in three separate thicknesses, and composed of two red pieces, occupying the back and front, with a blue piece interposed between them; for if the eyes are exposed even momentarily to the full glare of a large arc, an effect is produced upon the muscles of the eye which, though not permanently injurious, or of more than a few hours' duration, is very painful and disagreeable while it lasts. The effect produced upon the face or other tender portions of the skin by exposure to the radiant energy of the arc, for any length of time—although not felt at the time of exposure—is similar to that produced by a very severe sun-burn, and also painful when an attempt is made to wash the parts with soap. With these precautions taken, no trouble has ever been experienced, and the same men are now at work welding who have been associated with the process since its installation, and with such a low E.M.F. it is impossible to get a dangerous or even unpleasant shock, consequently the machine or articles in circuit may be handled with impunity, and all the operations of welding, etc., carried on with the workman sitting or lying upon the articles being welded.

Necessary Precautions to Ensure Sound Welds.

1. The carbons used should be "uncoppered" and of one uniform quality, sound, and hard, and having a metallic ring when struck, and must burn with little or no dust deposit, otherwise the finely-divided carbon deposited on the weld may be absorbed by the metal, which will thereby be rendered brittle. 2. When "building up," the metal introduced into the weld should be as nearly as possible of the same composition as that of the article to which it is welded, and the workman should remove the slag formed on the surface of the weld from each layer added before commencing to add another one. In cases where the part to be "built up" projects above the neighbouring surface (as for instance, a wheel tooth), each layer of material added should be retained in position and prevented from flowing away while in a molten state, and this is best done—previous to the addition of each layer—by forming a ridge of finely-ground gannister clay round the circumference of the layer to be added. 3. When the metal in the vicinity of the arc has been under the action of the arc for a short

Digitized by Google

space of time, the heat gradually extends by conduction to the metal in the neighbourhood of the part operated upon, whereby the resistance of the metal to the passage of the current is increased, and, in consequence, admits of a longer arc being obtained than under conditions where the metal in the vicinity of the part operated upon is not so heated; and the workman should always endeavour to obtain these conditions of heating of the surrounding metal, and to finish off each layer under the action of a long and steady arc, so as to ensure the gradual solidification of the metal added, and its subsequent annealing by the gradual radiation of the heat from the part operated upon, when the carbon is eventually withdrawn and the arc broken. 4. In all cases where it is possible to do so, each layer of new material added should be hammered immediately the carbon is withdrawn and the arc broken; and where this is not possible, the withdrawal of the carbon and breaking of the arc should be gradual, for reasons already stated.

QUALITY OF WORK DONE BY THE BENARDOS PROCESS.

In order that the capabilities of the Benardos process of electric arc welding in relation to the quality of work done might be placed beyond doubt, Mr. Henry Lea, the well-known electrical engineer, of Birmingham, was requested by Messrs. Lloyd and Lloyd to conduct for them an investigation in conjunction with Messrs. David Kirkaldy and Son, of London. For this purpose 210 bars of varying thicknesses and qualities of iron and steel were electrically heated and welded by ordinary workmen (not trained smiths), and, together with 50 bars welded by good engine-smiths in the employment of another firm out of a coke fire in the usual way, were submitted to Messrs. Kirkaldy to be tested. In the results, as reported by them, the "average ratio of weld to solid" of the 150 electrically-heated iron bars equalled 85·5 per cent., and of the 60 steel welds 80·8 per cent. In every case 10 welds of each size were tested. A comparison between the results obtained from the hand-welded bars and those which were electrically heated will show that in every case the latter give a higher "ratio of weld to solid" than the former. In other respects, also, the comparison is usually favourable to the electrically-heated bars. These experiments are believed to be the first attempt to demonstrate scientifically the value of the arc as a heater of iron and steel for welding purposes. It must be remembered, however, that the results shown were obtained by comparatively unskilled hands, and could be materially improved by continuous practice. The economy of arc heating in the manufacture at Coombs Wood and elsewhere of various articles is established beyond doubt.

In conclusion, the writer begs to point out that this process of electric arc welding is not proposed as a substitute in all cases for the ordinary methods of welding now in use, nor is it proposed as a substitute for riveting in the manufacture of high-pressure boilers, but rather as an additional method, capable of very extensive application under conditions where the ordinary methods of welding are inapplicable. The simplicity of the process, and the ease with which the working apparatus can be transported to the place required, combined with the nature of the work capable of being accomplished, as illustrated by the numerous examples given, are, in the writer's opinion, sufficient reasons for its more extended application; and the writer respectfully submits that it is difficult to conceive a more useful application of the process of electric arc welding than that which would be obtained from a small steam craft with the necessary welding plant and cables on board, and capable of plying up and down the river and effecting repairs of the nature of those illustrated, either in the works adjacent to the river while lying alongside a wharf or on board a ship when moored close by.

THE CANNON STREET EXPLOSION.

BOARD OF TRADE REPORT.

(Concluded from page 201.)

APPENDIX I.

(From the *Proceedings* of the Royal Society, vol. 56.)

"On the Difference of Potential that may be established at the Surface of the Ground immediately above, and at various distances from, a Buried Mass of Metal charged from a High-Pressure Electric Light Supply." By Major Cardew, R.E., and Major Bagnold, R.E. Communicated by Lord Kelvin, P.R.S. Received June 24, 1894.

On January 8, 1894, an accident occurred at Bournemouth of an unusual nature. An omnibus was in the act of drawing up in the roadway outside the Imperial Hotel, when the horses suddenly fell down, and one of them died in a few minutes. All the men who assisted in extricating the horses felt tingling sensations in their limbs suggestive of electrical shock, and the connection from the mains of the Bournemouth Electric Light Company to the hotel was known to pass underneath the spot at which the accident occurred. This company use the high-pressure alternating system at 2,000 volts pressure, and in the case of this hotel the transformers were installed upon the premises.

On investigation, a defect in the insulation of one of the high-pressure service lines was discovered, from which sparking had evidently taken place to the enclosing 1½in. wrought-iron pipe. This pipe was 32ft. long, laid at a depth of about 18in., and terminated at a brick junction-box under the roadway and a brick and cement area wall at the hotel. The ends were thus fairly insulated, while the rest of the pipe was in contact with the earth. The accident took place during the progress of a thaw after a very severe frost.

Upon consideration of the case, Major Cardew reported to the Board of Trade that in his opinion the accident was caused by leakage from the short length of charged pipe, affecting the potential of the surface of the ground to such an extent that between the fore and hind feet of the horse a sufficient difference of potential was established to give rise to the current which proved fatal. At the same time, as the fact of such a result following from a simple contact with ordinary road material was a new experience of the possible dangers attending the commercial supply of electrical energy, it was thought desirable to repeat the conditions as nearly as possible, and measure the results obtained. As such an experiment could not, for obvious reasons, be satisfactorily carried out in London, it was arranged that it should be tried at Chatham, where the necessary apparatus was available.

A first experiment was made on January 26, 1894. In this a length of 33ft. 3in. of 2in. iron pipe was buried to a depth of 18in. within the salient of one of the demi-bastions of St. Mary's Barracks, Chatham. A piece of well-insulated 37-strand No. 16 cable was inserted in this pipe so that the ends of the conductors made good contact with the inside of the pipe at its centre point. Over the centre of pipe two 56lb. weights were placed on the surface of the ground, and at a distance of 4ft. laterally another pair of 56lb. weights were similarly placed. A 16-kilowatt alternator was connected by mean of an underground cable laid in stoneware pipes to the piece of cable in the 2in. pipe. The other pole of the alternator was connected to a 1½in. service pipe in connection with the barrack water-mains. One end of this service pipe was in connection with a hydraulic ram set in the ground at a distance of 140ft. from the piece of buried pipe. An 800-volt Thomson static voltmeter was connected across the terminals of the alternator, and a pair of leads well insulated were attached by means of screws to the two pair of weights situated over the buried pipe. These leads were ran back together to the experiment-room, and were connected alternately to a 140-volt static voltmeter and a Cardew voltmeter.

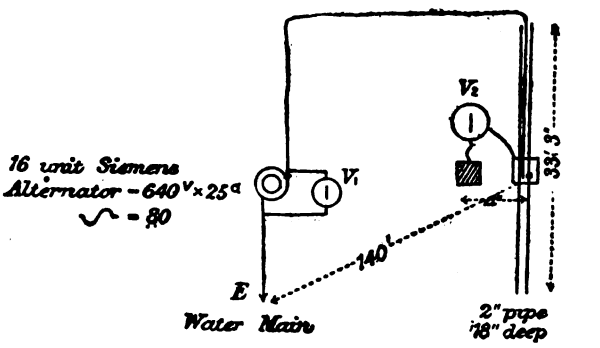

FIG. 1.

The voltage of the alternator was varied by means of the exciting current, which was taken from accumulators. The readings on both voltmeters are given in Table I. As the earth resistance was rather low, the alternator could not be run up above 400 volts without overheating the armature. Fig. 1 is a diagram of the arrangement.

TABLE I.—Experiment of January 26, 1894.

Readings of statical voltmeter on terminals of alternator.	Readings across weights.		Remarks.
	On Cardew voltmeter.	On statical voltmeter.	
294	—	62	Resistance of earth circuit before run, 17 ohms.

305	30	—	
310	30	—	
375	38	—	Distance between weights, 4ft.; weights, each, 2/56lb.
380	40	—	
400	43	—	
390	—	83	
375	—	81	Soil loamy and very wet.
385	—	82·5	
390	—	83	About 80 periods per second.
394	—	84	
400	—	86	
398	—	85	
400	—	86	
403	—	87 5	

The results show a potential difference between points 4tf. apart on the surface of over 20 per cent. of the whole potential difference used to charge the pipe when measured statically, and even when a current of nearly $\frac{1}{10}$ ampere was drawn from the

Digitized by Google

ground through a Cardew voltmeter the potential difference was more than 10 per cent. of the whole.

The propinquity of the scarp walls, however, appeared likely to have, to some extent, influenced the direction of the lines of flow of current, and it was determined to repeat it, changing the position of the pipe and extending the tests to a greater distance from the pipe. The second experiment was carried out on March 16, 1894. The arrangements are shown on Fig. 2, and the results given in Table II. The statical potential differences to be observed extended rather beyond the range of one voltmeter. Thus, between weights A and B no statical observations could be taken beyond a charging pressure of 440 volts, while between weights C and D the potential difference, even with 610-volt charging pressure, was too small for exact measurement.

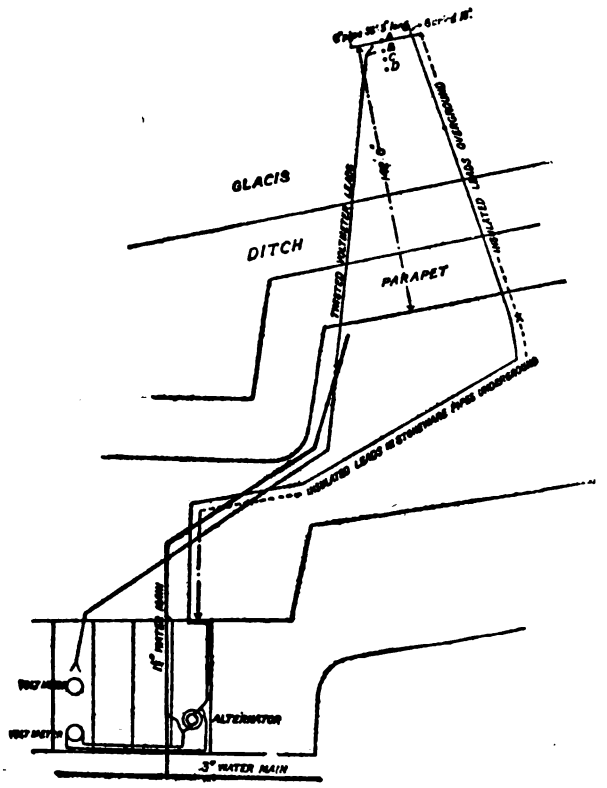

FIG. 2.

570	66	—	large for statical
600	70	—	voltmeter.
610	70·75	—	
620	71·5	—	
620	73	—	

An interesting note made on this experiment is as follows: "The soil in which the pipe was buried was loamy, and when digging the trench no worms were noticed, but towards the conclusion of the experiment it was observed that hundreds of worms came to the surface between 3ft. and 9ft. on either side of the pipe; no worms appeared, however, immediately over the pipe." The ground was much drier than was the case in the first experiment, and, probably in consequence of this, it appears that while the statical potential difference between the two first weights is relatively greater in the second than in the first experiment, the potential difference obtained with a current-using instrument is relatively less.

By interpolating an approximate value for the fall of potential between A and B from the readings obtained on the Cardew voltmeter, a rough curve of the fall of potential on the surface of the ground, for a charging pressure of 610 volts is obtained, as shown in Fig. 3, Curve *a*, the height of the curve above absolute zero being made consistent with the evident approach of the curve to its asymptote at D. In this case, therefore, the effect of the leakage extended to a distance of about 14ft. from the pipe, and the fall of potential on the surface appears to have been most rapid at a distance from the line immediately above the pipe equal to twice the depth at which it was buried.

A third experiment was carried out on May 22, 1894, with the same arrangements as in the second experiment. The objects for which this was undertaken were chiefly to obtain a record of the variation of potential difference on the surface with the charging current, which had not been previously recorded, to obtain results from charging with continuous as well as alternating current, and to extend the investigation as regards the latter. Unfortunately, the continuous-current generator could not be used, owing to a mechanical defect which could not be removed in the limited time available. Still, the results obtained with

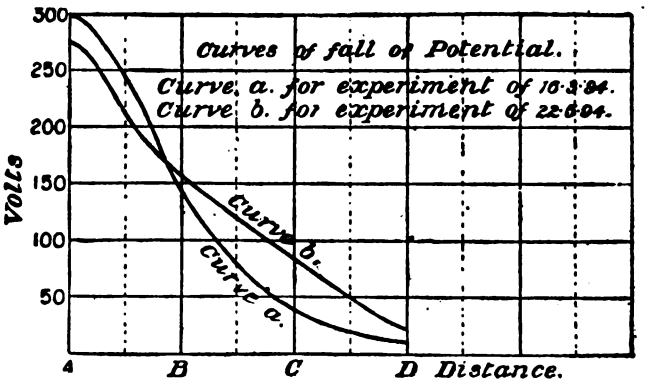

FIG. 3.

alternating current are, it is considered, of some value, especially as the condition of the ground was different from that which existed at the time of either of the two former experiments, it being wet on the surface with rain falling during a portion of the time, and dry underneath. Curve *b* in Fig. 3 appears to show by its form the effect of this state of the soil, the fall of potential from B to D being approximately indicated by a straight line—that is to say, that the current flow was practically entirely confined to the surface layer. The curve is deduced from the results of experiments shown in Table III. for a charging pressure of 550 volts.

In order to obtain a direct indication of the statical potential difference between weights A and B, the voltmeter which had been used for recording the charging pressure was connected to these points and observations taken, when the exciting current for the field magnets of the dynamo and the charging current to the pipe were practically the same as in a previous set of experiments, for which the charging volts were known. Both sets of experiments are shown in the table. The disturbance of the worms was again very distinct, and they appeared on reaching the surface to set their bodies parallel to the pipe or along an equipotential line.

The experiments as a whole show conclusively that under very different conditions of weather and amount of moisture in the soil it is possible to produce a fall of potential amounting to 25 per cent. of the whole pressure in the supply between points on the surface of the ground 4ft. apart, a distance which most horses stand over, and, further, that although the connection of such points by a conducting body naturally reduces this potential difference, yet when this conductor has about the resistance of a horse (say, 400 ohms), sufficient current will pass to give a severe shock. It is hoped that when opportunity serves these experiments may be extended to the case of pipes buried to greater depths, and to observe whether any difference is produced by the use of a steady in place of an alternating pressure.

APPENDIX II.

Extracts from the Regulations for Securing the Safety of the Public, etc., made by the Board of Trade under the Provisions of the Electric Lighting Acts, 1882 and 1888, and of the City of London Electric Lighting Orders, 1890 and 1891.

(7) Where any high-pressure conductor is laid in a subway, or in the same conduit with any low-pressure conductor, it shall be completely enclosed in strong metal casing efficiently connected to earth.

(8) Where any high-pressure conductor is laid within a less distance than 18in. from any low-pressure conducter or from the surface of the ground, or where any low-pressure conductor is laid within the above-mentioned distance from any previously-laid high-pressure conductor, efficient means shall be taken to render it impossible that the low-pressure conductor or the surface of the ground shall become electrically charged by any leakage from or defect in the high-pressure conductor.

(14) Every conduit for conductors constructed in streets in which gas-mains are also laid shall be efficiently protected against an accumulation of gas.

(15) Where a street box contains any high-pressure conductor, efficient means shall be taken to render it impossible that the cover or other exposed parts of the box, or any adjacent material forming the surface of the street, shall become electrically charged, whether by reason of leakage, defect, or otherwise; and every street box shall be efficiently protected against any accumulation of gas or water, and its cover so secured that it cannot be opened except by means of a special appliance.

INSTITUTION OF ELECTRICAL ENGINEERS, Feb. 21.

PROF. GEORGE FORBES in the chair.

The **Chairman** stated that Mr. Crompton was unable to be present, in consequence of having been summoned to the Continent. Without calling upon the secretary to read the minutes of the previous meeting, he asked Dr. Hopkinson to read his paper (of which we give an abstract) on

Propagation of Magnetisation in Iron.

BY J. HOPKINSON, F.R.S., PAST-PRESIDENT, AND E. WILSON, MEMBER.

The paper deals with the same subject as was dealt with by the same authors at a meeting of the Royal Society on May 31, 1894, but the experimental work is carried out with larger apparatus. It has, of course, been long known that in electro-magnets with solid cores currents are induced in the solid iron when the magnetising current is reversed, and that these currents for a certain time retard the development of changes in induction. The length of time that these currents exist will be surprising to many. In the experiments shown, a magnet of 12in. diameter was used, and exploring coils are buried in its substance. These show how the change in induction occurs extremely rapidly near the surface of the magnet, less rapidly at some depths, and slowly at its centre. With certain magnetising forces it takes as much as four minutes before the change at the centre of the core attains a maximum. The application of the results to magnets with cores of other sizes was pointed out, and conclusions were drawn as to the appropriateness of general practice in regard to the sizes of wires or plates used in transformers. The experiments were made in part with the reversals of current in the magnetising coils, and in part with the currents of a slow alternating character. The slow alternating currents were produced by means of a liquid reverser substantially similar to one which was described by Prof. Ewing.

DISCUSSION.

Dr. Fleming, who opened the discussion, said that it was with great delight they had seen the experiments given by one who was a master of the subject. He referred to some experiments made by the author and himself in 1882 at Messrs. Brotherhood's with different forms of dynamos. In one machine Dr. Hopkinson had abolished the multiple legs, and had substituted great oval legs. When that machine was tried it took ten minutes or a quarter of an hour to excite itself. He subsequently tried a Jumbo Edison machine. The field magnets were taken to Ponders End. On one occasion the cores were joined in series and current passed from a secondary battery to magnetise the field magnets, a galvanometer being inserted in series. Their astonishment was great to find that the current required six or seven seconds to become steady. The field magnets were 6in. or 7in. in diameter. Thus the figure practically agreed with that the author had mentioned. It was useless to employ solid conductors over a certain diameter for alternating currents, and hence Mr. Ferranti had adopted tubes for the Deptford mains to London.

Captain Creak, who referred to the electric lighting of war vessels, stated that they had a number of ships in which there was a pair of dynamos placed symmetrically one on either side of the compass. The consequence was that if they ran the port dynamo at night, and the starboard remained idle, they would have a change of some 4deg. in the course, or, at 19 knots, about 150 miles in the result. But by using the starboard dynamo as a corrector that was absolute.

Mr. W. H. Mordey was glad to find that the kind of lamination adopted in transformers had been confirmed by the researches brought before them. An important point touched upon was the excitation of a solid core by a redressed current. He had designed large alternators with large solid cores, the magnets of which were excited by redressed alternating currents. To his surprise he found that it required the same current to excite them, and that the watts taken were very little higher than with the direct current. The power factor was ·7, and there was no marked absorption of power. Apparently with the redressed current the magnet settled down to some steady condition, and there was very small surface fluctuation. That was the kind of explanation that occurred to him at the time. Could the author throw any light on the matter. The speaker then referred to some experiments made by Prof. Hughes.

Mr. Evershed discussed the question of the penetration of induction to the core, and the use made of mathematics in relation to the subject.

Mr. G. L. Addenbrooke considered that the author's experiments bore an important point in regard to the design of alternators. The self-induction between the armature and the magnet depended upon the permeability of the magnet. It was evident whether they had a large and massive field in the alternator that the self-induction could not rise to the amount that they would anticipate in the ordinary way, and that, therefore, the reaction of the armature on the field magnets could not be so great as would otherwise be expected.

Prof. G. Forbes, who regarded the subject as one of the greatest difficulty to attack, referred to the Gaulard and Gibbs patent case, and to the statement made on that occasion by Lord Kelvin that the difference between a laminated core and a solid one was known. He did not know whether Lord Kelvin went into mathematical calculculation and applied it. Dr. Hopkinson, however, left out the mathematical calculation, and tackled the subject by experiments. He thought that the striking part of the experiments was the way in which No. 1 coil did not move under the influence of changes in the induced currents surrounding it, until the effect of the induced currents of No. 2 had ceased. With regard to Captain Creak's remarks, why did not the Admiralty adopt ironclad dynamos, and the difficulty of affecting the compass would be overcome.

Dr. Hopkinson, in the course of his reply to the discussion, stated that the galvanometers used at the meeting were of the Ayrton and Mather type, made by Mr. Paul. He paid a tribute to the assistance rendered by Mr. Wilson; in fact, the latter had done much original work. He was also indebted to some of the student demonstrators from King's College, Messrs. Cobb, Evans, and Mokofsky.

Votes of thanks were passed to the authors, to the Council of the Society of Arts, and to Sir Henry Trueman Wood and his staff. The next meeting of the Institution was announced for Thursday of next week.

Temporary Lighting of Vessels.—Some time ago we referred to the steps taken by an electrical firm to induce the owners of the vessels patronising the Manchester Ship Canal to avail themselves of portable electric lighting plant for making night passages through the canal. We now note that the Compagnie Nationale d'Electricité, of Caen, are about to follow this example in regard to the lighting of vessels passing from Caen to the seaboard. The company will undertake at their own risk the electric lighting of the vessels on payment of an annual subsidy of £24 for at least five years, and a certain charge per ship. The charge, which will include the provision of five portable batteries and a projector of 200 c.p., will be as follows:

For vessels up to 600 tons	£1	8	0
,, from 600 to 800 tons	1	12	0
,, ,, 800 to 1,000 tons	1	16	0
,, of and above 1,000 tons	2	0	0

SUBMARINE CABLES IN WAR TIME.

Lieutenant-Colonel H. Elsdale, R.E., contributes an article to the current *Nineteenth Century* on the question, "Should we hold on to the Mediterranean in War?" The author comes to the conclusion that we ought to abandon the Mediterranean, but he puts the points against such an act very fairly, and, among other things, he says:

"It is, perhaps, of greater importance that by losing Egypt we shall lose our telegraph lines to the East, which pass through the Isthmus of Suez. This is undoubtedly a serious matter. *The evil will, however, be minimised by the lines round the Cape and across Canada.* [The italics throughout this quotation are ours.] In any case, and apart from the present question, it is of the *first importance that we should secure continuous submarine communication* with all our leading stations abroad, with no such weak links as that at the Isthmus. This is undoubtedly a pressing matter, whatever be our precise strategy in war."

The holding of the Mediterranean at all cost has probably been the foremost idea of most Englishmen who have hitherto studied the question, but Colonel Elsdale makes out a very good case. To an ordinary mind, the loss of command of the Suez Canal and through the Mediterranean means danger to India and our Eastern possessions. The author we have quoted, on the contrary, holds the abandonment of the Mediterranean means safety to our Eastern possessions, an overwhelming preponderance of force in our favour, and danger to the enemies' colonies. However this may be, the one question with which we have to deal is that pertaining to cables. Our readers know that the policy we have always advocated is in this matter that a Pacific cable ought to be laid, touching no possibly hostile territory, and going throughout through English possessions. We even would go so far as to have the cable direct from England to Canada, and not from Ireland to Canada. Under the conditions laid down by Colonel Elsdale, at the present moment we have absolutely no safe way of telegraphically communicating with the East. Every cable has ends somewhere or other on what would be hostile territory. He is in error when thinking, as he seems to think, that we have an alternative way to the Cape by the West Coast route. This cable is a succession of links—some of the ends of the links, as we say, touching hostile territory. The Indo-European, or overland, route will not help us at all, as this goes through what might be an enemy's country. The policy of the late Sir James Anderson—for he was really the originator and brainworker of the two—and Sir John Pender—who is not and never has been more than the spokesman—was to have the cable in sections, as conducing more to tap commercial centres, than in direct routes. We have no objection to this policy, and would admit, from a commercial standpoint only, it is probably the best way of making cables pay. From an Imperial point of view, however, we doubt if the policy is correct. We have often heard the argument for what we may term the loop system in war. The line may be easily cut, but it also can be easily repaired.

Digitized by Google

There would be little difficulty in laying a duplicate cable, cutting out any loop that touched upon hostile territory. That is quite true, and there is much to be said in favour of this plan; but there is also one great and overwhelming objection to it: these duplicate loops are not laid, and never will be laid, by private individuals seeking a return for capital expended. The question then resolves itself into this, Will the Government lay the necessary loops purely for Imperial purposes? They are not wanted commercially, so there would be no return for the capital expended. Or, will the Government, in conjunction with the colonies, lay a Pacific cable which should be both effective for Imperial purposes and at the same time have a greater or less commercial value? When we consider the value of cable communication for purely Imperial purposes, the same considerations as when thinking of trade do not arise. It is essential, when considering our colonial possessions, that in times of war we have, so to say, free speech with them without danger of any adversary knowing what is being said and done. Wars cannot be carried on nowadays as they were in olden times, when years might be spent in preparation, as well as years in conflict. Modern wars promise to be short and sharp. A few months, and a nation is lost or saved. To England, it would seem, then, of vital importance not to shilly-shally over questions of such vital importance in the inane meanderings which now constitute the bulk of parliamentary work. It is very well to say that at the commencement of all her great wars this country was found unprepared, but that she made gigantic efforts during the progress of the wars, and finally came out victorious. All that has changed, and, as said before, it is very doubtful if time will be obtained during the next war to make defects good and to do work which ought to be done during the piping times of peace. From the estimates sent in, we have seen that the Pacific cable can be laid for considerably less than was at one time supposed, and it only requires the co-operation of our Government with colonial efforts to have that cable complete and in working order by the end of 1896. From the importance of the matter, and from the information given in Mr. Sandford Fleming's memorandum, it would seem that the commissioners representing the parties interested need not take long to come to a final understanding on the whole matter.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

WATER-POWER INSTALLATIONS FOR ELECTRIC LIGHTING.

SIR,—Referring to the contribution in your last week's issue by Mr. E. R. Dolby upon "Water-Power Installations for Electric Lighting," although we fully agree with that gentleman that water-power schemes are frequently delusive (and we speak feelingly, for much of our time has been wasted in explaining that ½ h.p. will not light a large house), yet we think that the paragraph you were good enough to insert in the same issue upon "Electric Locomotives in Mines" provides another side to the question, as the whole of the pumping, hauling, lighting, winding, etc., in the mine referred to is performed entirely by water power—about 100 h.p. in all.

We are induced to write this as we think that Mr. Dolby's remarks may be interpreted (or rather misinterpreted) to condemn the use of water power in this climate.

Yours, etc.,

THE ACME AND IMMISCH ELECTRIC WORKS, LIMITED.
(H. Twelvetrees, Secretary.)

London, February 19, 1895.

REVIEWS.

Steelworks Analysis. By J. O ARNOLD, F.C.S., Professor of Metallurgy at the Sheffield Technical School. London: Whittaker and Co. Price 10s. 6d.

Those who have watched the enormous development in the steel industry during the latter half of this century will know how closely and continuously scientific investigation goes on at all large works. The Iron and Steel Institute is a noble monument to the untiring activity of those engaged in the industry, for the pages of its *Transactions* contain a mine of useful knowledge culled and contributed from the four quarters of the globe. Text-books, elaborate and otherwise, have been written, yet withal there is plenty of room for this work of Mr. Arnold's. This is not the place to discuss at any length the properties of steel that make it valuable, or the impurities likely to arise in the manufacture which may impair that value. The author commences by discussing the design and equipment of a works laboratory; then, in Section I., he plunges into the practical work, describing the constituents and possible impurities of steel, giving a clear and concise account of the various analytical processes worthy of notice, illustrating where necessary. So far as we can judge, extraordinary care has been taken throughout to ensure accuracy, and great pains have also been taken to make every process clear to the reader. The next section deals with the analysis of iron ores, and is as good as the preceding one. A section on refractory materials is followed by one on fuels—a most important branch of the subject. A section on sundry processes, principally dealing with slag, is followed by an appendix; and a fairly good index concludes a book which for clearness of exposition and general value to the steelworks chemist, and especially to the younger men, it would be difficult to surpass.

A Treatise on Industrial Photometry, with Special Application to Electric Lighting. By Prof. A. PALAZ, Sc.D. Translated from the French by George W. Patterson, jun., M.A., B.S., and Merib Rowley Patterson, B.A. New York: D. Van Nostrand Company. London: Sampson Low, Marston, and Co.

This is a long title to a good book—good in more than one way, in that it for the first time treats this subject exhaustively, and in that both method and subject-matter merit praise. The principles of photometry are first explained; the intensity and the various actions of light are then discussed. It would be almost possible to construct a good description of the subject by quoting some of the summarising and the defining paragraphs of the author. Here is an example:

"From a photometric point of view, the only radiations that are to be taken into account are those which are perceptible to the eye" (p. 9).

"The eye is then the standard piece of apparatus for all photometric operations: it is the photoscope required for every comparison of intensity of two luminous bodies—the eye here plays the same *rôle* as the galvanometer or the electrometer in electrical measurement by zero methods. We can therefore only tolerate for photometric measurements a healthy and well-formed visual organ. Furthermore, the obligatory employment of the eye imposes in photometric measurements a limit of precision determined by the sensibility" (p. 10).

Digitized by Google

"The sensibility of the eye varies with the nature of the luminous rays" (p. 12).

"A body when heated sends forth rays—that is to say, it causes a vibratory movement of the ether, the nature of which depends on the temperature" (p. 14).

"The intensity of a source of light varies, in general, with the direction of the luminous rays. . . . If we lay off in various directions lines passing through the luminous source, whose lengths measure the intensity of the rays emitted in these directions, the *locus* of the points thus obtained forms a surface called the *photometric surface* of the source. In arc lights, for instance, the photometric surface may be considered, in general, as one of revolution about the common axis of the two carbons, although, in many cases, this condition is not perfectly fulfilled, on account of defects in the homogeneity of the carbons and in their centreing" (p. 17).

We could, as we say, construct a readable article of such quotations, but such is not our purpose. The author having discussed the principles of photometry, goes on to describe the various photometers that have been devised since the first used by Lambert in 1760, of that known as Rumford's, to the latest. These descriptions are full without being verbose, and, when necessary, illustrated. Then the question of photometric standards is discussed at considerable length, all the more important standards being described and compared. Of course, more careful attention and description is given of Violle's standard as adopted by the International Congress of Electricians in 1881. The resolution adopted by this congress is as follows:

"The unit of each simple light is the quantity of light of the same kind emitted normally by one square centimetre of surface of melted platinum at the temperature of solidification."

"The practical unit of white light is the quantity of light emitted normally from the same source" (p. 163).

Then follows a chapter on the general equipment of a photometric laboratory, after which is one of nearly 70 pages on photometry of electric light. Much of this information has at various times appeared in the technical papers, yet there is much information we should like to quote, but it would take up far too much space, and interested readers must obtain the book itself. No quotations will prove its value—only a careful study of the whole. The concluding chapter is also an important one—on the distribution and measurement of illumination—a branch of study most electricians are imperfectly acquainted with, being satisfied to work by rule-of-thumb. The translators have added a short appendix. Altogether, this work is exceedingly valuable for its completeness, simplicity of treatment, and mass of information collected. The translators have done their part of the work well.

NEXT WEEK'S NEWS TO-DAY.

The electric light in the Church of St. Peter, Eaton-square, W., is most unobtrusively placed, and is a great improvement, as it will help to preserve the exceptionally beautiful mosaics which cover the walls of the sanctuary, and which are such a feature of the church.

An amusing incident took place at the Royal United Service Institution on Wednesday afternoon when members of the Royal family were trying the telautograph. The Prince of Wales sent a message to the Duke of Connaught at the other end of the building. The Duke smartly replied in a firm, bold hand, "When you next write to me please make your handwriting a little more distinct." The Prince roared with laughter. His handwriting was probably affected by his cold.

M. Emile Gautier, the well-known *savant* who has for many years contributed articles on scientific subjects to the *Figaro*, has just placed himself at the head of a literary undertaking to which everyone must wish success. It is a weekly periodical for popularising science, entitled *Science Française*. Among the contributors will be Prof. Chantemesse, Inspector-General of the Sanitary Services; Prince Roland Bonaparte; M. Germain Bapst; M. Maurice Leblanc, the well-known electrician; Sir John Lubbock; M. Bonvalot, the explorer; and M. Janssen, of the French Institute.

So we are to have mica from Canada. Mr. Harrison S. Watson, of the Canadian Section of the Imperial Institute, Imperial Institute-road, Kensington, S.W., informs us that Dr. G. M. Dawson, the director of the Geological Survey of Canada, has sent him a collection of some 50 samples of Canadian mica. The export of this article from Canada to the United States for electrical purposes has steadily increased, and Dr. Dawson has requested Mr. Watson to call the attention of English electrical manufacturers and others to the qualities of the Canadian mica with a view to its further introduction into British markets. The samples of mica are on view in the Canadian Section at the Imperial Institute, where they may be inspected between the hours of 10 a.m. and 4 p.m.

BLACKBURN ELECTRICITY WORKS.

The formal opening of the electricity works at Blackburn, which we described in our last issue, was performed on Monday by the Mayor (Alderman R. T. Eastwood), in the absence, through illness, of Alderman W. Thompson, the chairman of the Gas Committee. The Mayor was accompanied by most of the members and principal officials of the Corporation, and there were also present representatives of the consulting engineers and contractors engaged in carrying out the works, including Mr. A. S. Giles (the recently-appointed resident electrical engineer) and Mr. Alex. Siemens (principal of Messrs. Siemens Bros. and Co., Limited). The company first assembled in the building where the dynamos and engines are located. The formal proceedings commenced by the Mayor asking the engineer to start the engines, and this having been done, his Worship switched on the current and declared the installation complete, hoping it would prove the great success which the Gas Committee and Corporation anticipated. The company then adjourned to luncheon in an upper room of the building.

The MAYOR, in rising to propose "Success to the Blackburn Electric Lighting Installation," deeply regretted the absence of Alderman Thompson, and remarked on the pleasure it would have given all present to hear the worthy chairman give some facts and figures with regard to a work in which he had taken such increasing interest. It might be that he (the speaker) was somewhat of a pessimist, but he could hardly think that at present, at all events, the Corporation would make more than the interest on the money they had laid out on the electric lighting plant, not to name a profit at all; but he hoped there would be such a healthy competition and rivalry for the new illuminant amongst the tradesmen of the town that the works would soon be a paying concern. The Corporation had expended up to the present time between £17,000 and £18,000. They had sanction to spend £32,000, but they intended to keep well within that limit after they had extended the plant sufficiently to meet the requirements of everybody in the extended area. After complimenting the contractors on the manner in which the various works had been carried out, the Mayor expressed the hope that the consumption of gas would increase along with the use of electricity, and he stated that close upon 3,000 of the 10,000 lights which the works at present are calculated to supply were already applied for, and before the end of this year he hoped from half to three-fourths of the total number would be connected.

Mr. ALEX. SIEMENS responded, and gave some details of the Blackburn installation. He congratulated them on having adopted direct driving and the low-pressure three-wire system. Speaking as one to whom it did not matter whether he fitted up gas or electricity works, he could give them the best appliances for either; he could safely predict a great success for the installation, and said he did not see any reason why the Corporation should not soon be receiving 7 per cent. on their outlay, as was the case in Bradford.

Councillor HAMER, in proposing the health of the chairman of the Gas Committee, paid an excellent tribute to the capabilities of Alderman Thompson, not only as regarded the work they had just seen brought to an issue, but with regard to everything he undertook, and remarked that those who opposed could but respect him, for he never deceived anyone by a trick of language.

Alderman T. E. THOMPSON responded on behalf of his uncle, and reciprocated the kindly feeling and the good wishes.

Digitized by Google

Alderman RUTHERFORD submitted the toast of "The Mayor and Corporation of Blackburn" in an effective speech. He complimented his Worship on the able manner in which he had presided over the town's affairs since his election. The Corporation deserved well of the public, seeing that they had carried out so many important works without raising the rates above the average of those in other large industrial towns.

His WORSHIP, in responding, remarked upon the pleasantness of mayoral duties with such willing and considerate townsmen to make them light.

Councillor KENYON also responded on behalf of the Corporation, and other toasts brought the proceedings to a close.

THE PACIFIC CABLE QUESTION.

An important memorandum by Mr. Sandford Fleming respecting the establishment of the Pacific cable has been made public in Canada. It gives information up to date of the progress made with the scheme since the meeting of the Ottawa Conference, and states what are understood to be the accepted views of the Canadian Government.

Acting under the resolution of the conference, which requested that the Canadian Government should take the necessary steps to promote the construction of the cable, the Dominion Government called for tenders under three forms. By the first of these, Form A, the cable is to be owned and controlled by Government, to be worked under Government authority, and to be kept in repair by the contractor for three years. The only actual offers received are, Mr. Sandford Fleming informs us, according to this form, and he proceeds to state that: "Among the tenders received is an offer from an old-established and reliable firm to lay the cable on route No. 1—the all-British route by Fanning Island—for the sum of £1,517,000. This price includes maintenance and repairs for three years after the whole line shall have been completed and put in operation; consequently, there would be no disbursement for these services during this period to be met by the earnings of the telegraph. The cost of working and interest on capital would be the only charges against revenue during the first three years after the cable shall have been laid."

By this offer it is made clear that the assent of the Hawaiian Government to the proposal of Great Britain to lease Neckar or Bird Island for the purposes of a telegraph station is not considered by cable manufacturers as by any means necessary to the successful laying of an inexpensive line of cable communication across the Pacific.

Mr. Sandford Fleming is strongly in favour of the principle of State ownership of the cable. On this subject, after referring to former occasions on which he has maintained that it would be unwise to subsidise a company when the object in view can more economically and with greater advantage to the public be attained by other means, he says: "It has since been suggested as an alternative to a subsidised company (Form B) to establish a company under a Government traffic guarantee (Form C). That is to say, the company to be guaranteed a gross revenue from traffic for a term of years; the deficiency between actual earnings and the guaranteed earnings to be made good by the Governments each year. To my mind, this plan is scarcely less objectionable than the first-mentioned. Let us, by way of illustration, assume that a company is formed under a Government guarantee of gross traffic equal to £200,000 per annum for a period of 25 years. What, in this case, would prevent the existing company and the new company entering into a secret pooling agreement by which it would be the policy of both to pass over the old line the great mass of the traffic, the object being to establish against the Governments each year of the 25 as large a claim as possible under the guarantee? I do not see that it would be possible to prevent the two companies amalgamating their interests in this or in some other way; and, as a consequence, a powerful monopoly would be built up to exact its own terms. Looking at the subject in all its bearing, the true plan, in my judgment, is to make the Pacific cable a public undertaking from its first construction. I am satisfied the more the subject is considered, it must become clear that only by the observance of the principle of State ownership will the greatest public advantage be permanently obtained. If, in establishing the Pacific cable as a public undertaking, the co-operation of the mother country with Canada and the Australasian colonies be secured, the most advantageous consequences will undoubtedly proceed from this arrangement. The first effect of co-operation would be in connection with the initial cost of the work, as a joint guarantee would admit of the required capital being raised at the lowest possible rate of interest."

Assuming the principle of co-operation and State ownership to be assented to, Mr. Sandford Fleming calculates the cost of the undertaking as follows: "Should the most costly of the several routes which have been spoken of be adopted—that is to say, the route by Fanning Island, with branches to New Zealand as well as Australia—I am unable to see with this tender before us, offering to complete it in every respect for £1,517,000, that the capital to be raised need exceed £1,600,000. This capital raised at 2½ per cent. gives £40,000 as the total interest to be met yearly. As it is advisable in forming an estimate of this kind to make full and complete provision for unforeseen contingencies of whatever kind, 10 or 12 per cent. may be added. In this view £45,000 may be considered the maximum interest charge, to which, if we add £30,000 for working expenses, we have the sum of £75,000 as the total fixed charges to be met by revenue in each of the three years after the cable shall have been opened for business."

This brings Mr. Fleming to the consideration of the question of probable revenue. On this point various documents are appended to the memorandum, amongst others, a statement drawn up by the Dominion statistician, Mr. George Johnson, showing the increase in Australasian telegraph business with Europe in the last 20 years to have been from 235 160 words per annum to 1,401,293 words per annum. Allowing for some continued increase, and for what is considered a fair division of the business with existing lines, it is estimated that the gross earnings at 2s. a word during the first three years of the operation of the cable would, as a consequence of the agreement with the contractor to maintain the cable in working order for that period, give a surplus of revenue over expenditure of £154,000 for the three years. After the third year the cost of maintaining the cable would be a charge against surplus earnings. Mr. Sandford Fleming states the position as follows: "The following table covers the remaining seven of the first 10 years after the opening of the telegraph for traffic, and is computed on the principles set forth in the appended papers. The cost of repairs and maintenance, usually estimated at £6 per mile, would amount to £43,000 per annum. For this service I have allowed £50,000, which, added to interest and working expenses, increases the charge against revenue to £125,000 per annum:

—	Gross earnings.	Charges.	Surplus.
Surplus for the first three years.....	—	—	£154,000
1901.....	£159,500	£125,000	34,500
1902.....	176,000	125,000	51,000
1903.....	192,500	125,000	67,500
1904.....	209,000	125,000	84,000
1905.....	225,500	125,000	100,500
1906.....	242,000	125,000	117,000
1907.....	258,500	125,000	133,500
Total surplus in 10 years.....			£742,000

Mr. Sandford Fleming is satisfied that his estimates are "reasonable and reliable." The first result of the Pacific cable from the mere reduction in rates alone will be, he claims, to effect a gross saving within a year after the cable shall be open of £190,000 in Australasia and the mother country.

The intention of his memorandum is briefly expressed in one of the concluding paragraphs. He says: "It has been my object to show by the facts I have presented and the figures I have produced that a mutual effort on the part of Great Britain and the two great divisions of the Colonial Empire can establish the Pacific cable with ease and practically without cost to the taxpayer in either country."

The memorandum has been communicated to the Imperial and Australasian Governments, and it is proposed that a joint commission composed of an Imperial, a Canadian, and an Australasian representative should meet in London to discuss financial and other details. The answer of the Australasian Governments to this proposal has not yet been received.—*The Times.*

THE "GLENBOIG" STREET BOX.

The recent explosions of gas in connection with underground mains should cause special attention to be paid to any methods designed with a view to overcome this difficulty. Among these may be mentioned the stoneware street boxes brought out by the Glenboig Union Fireclay Company, Limited, of 4, West Regent-street, Glasgow. The type of box illustrated in Fig. 1 is made in one piece, and is glazed both on the inside and outside. This box is arranged for both iron pipes and troughs, and is claimed to be both gas and water tight. The conductors and leading-in ways are packed at the entrance to the box with yarn, whilst the iron cover is set in red lead. The box, which is made in various forms and sizes so as to meet any requirements, has been approved by many electrical engineers. In our second illustration is given a section of a transformer-box, also made of stoneware. It will be seen that a stoneware support perforated so

Digitized by Google

as to allow the insulating oil to enter is provided for the accommodation of the transformer, the conductors entering the box

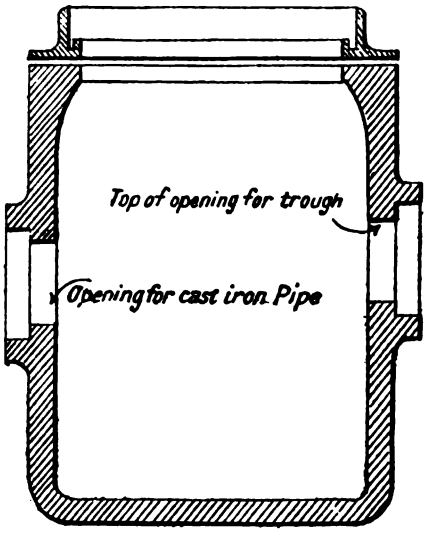

Fig. .—" le boig " Stre Box.

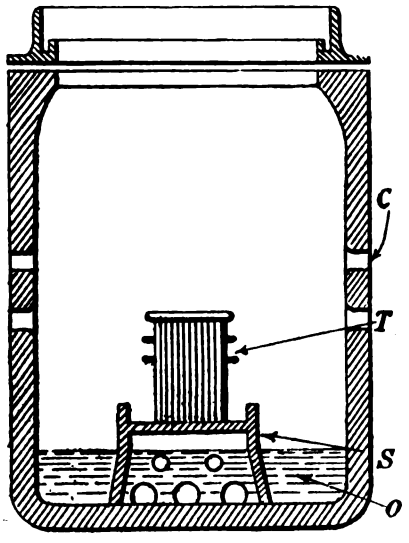

FIG. 2.—" Glenboig " Transformer Box.

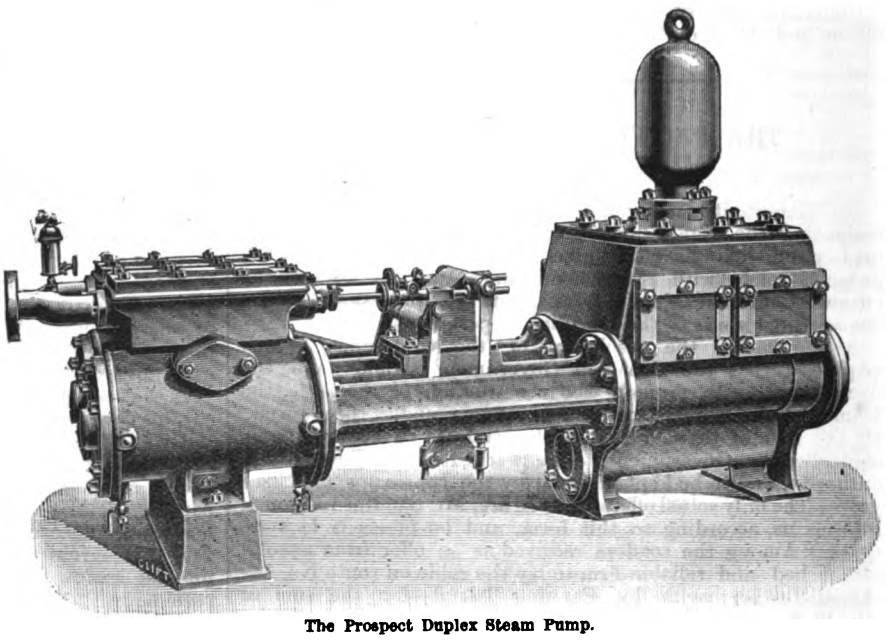
being packed, as shown in Fig. 2. C shows where the conductors are brought in, T represents the transformer, S the support, and O the oil.

THE PROSPECT DUPLEX STEAM-PUMP.

In a recent issue reference was made to the duplex steam-pump made by Messrs. Cole, Marchent, and Morley, of Bradford, and we are now enabled to give an illustration of it. It is claimed that this pump, which has been devised by Messrs. Holehouse and Morley, is the only direct-acting pump which can use the steam expansively and make regular strokes. The great feature of this pump is that the steam in each cylinder is distributed in each cylinder by means of a double or compound motion, each side having part control of its own and its neighbour's valve, and with a rigid connection to the valve this will enable the pump to be worked expansively according to the relative proportion of the levers. A suitable proportion has been arrived at for general work, and to enable the engine to be easily started and run slowly, the hand wheels, shown on the valve spindles of the illustration, are provided to give adjustment to the expansion from about seven-twelfths to full length of the stroke, which adjustment can be made and easily seen by an outside indication whilst the engine is in motion. This simple alteration to the old duplex action, the makers state, gives more advantages than may appear at a first consideration. The compound action causes the pumps to run nearly as though they were coupled to cranks at right angles, and they only pause to allow of reversing the stroke. Consequently, as both pumps are always in motion, this pump at the same speed will, it is claimed, lift twice what is lifted by the ordinary duplex pump, for the ordinary duplex pump wastes half its time with the pause at each end of the stroke.

The steam also is stopped entering the cylinder before, or directly it has got to, the end of its stroke, this effecting a saving of steam. By the same reason the compression is arranged for by the valve at the proper time, and can be adjusted by the wheels before referred to so as to suit the speed, pressure, or waterhead, and as the valve adjusts its own lead and compression there will be no short strokes, which is again a saving of steam. Messrs. Cole, Marchent, and Morley state that only at starting a pump arranged for a heavy head, without any head on the pump, is any bumping of the covers likely to occur, and that this is prevented by the addition of a compression port. When the pump is once started the delivery



The Prospect Duplex Steam Pump.

main may break, but the pump is very unlikely to bump the covers. If the arrangements are such that the pump can be worked expansively, it is impossible to bump the covers under any conditions. This type of pump, for which a large capacity, high efficiency, and saving of steam are claimed, is suitable for a variety of purposes, including the feeding of boilers, and as condenser pumps, etc.

LEGAL INTELLIGENCE.

GLYN v. PLANET ELECTRICAL ENGINEERING COMPANY.

In the Westminster County Court on Friday his Honour Judge Lumley Smith, Q.C., had before him the case of Glyn *v.* the Planet Electrical Engineering Company, in which the plaintiff sought to recover commission at the rate of 7½ per cent. on certain orders for electric light work obtained by him on behalf of the defendant company.

It appeared from the evidence of the plaintiff that he was formerly in the employ of the company as traveller, at a salary of £2 a week and 5 per cent. commission on the orders which he succeeded in bringing in, but some time ago the arrangement was put an end to, and it was agreed that he should have 7½ per cent. commission in lieu of salary. Upon that understanding he obtained several orders for the defendants, but when he made his claim for commission they declined tc allow him more than 5 per cent., which sum he refused to take, and then this action was commenced.

For the defence, it was absolutely denied that there ever was any arrangement made to pay the plaintiff 7½ per cent., or that he had ever been paid more than 5 per cent. It was further contended that the plaintiff was not entitled to be paid his commission until the defendant company received payment for the work, but, in spite of that, he had included some items in the present claim in respect of work which had not yet been paid for. The amount which the defendants admitted to be due to the plaintiff on the 5 per cent. basis was £3. 9s., and that sum had been paid into court as being the amount due up to the date of paying in.

His **Honour**, after hearing the evidence of the defendants' witnesses, said he was satisfied that the amount paid into court was sufficient, and gave judgment for the defendants, but without costs.

COMPANIES' MEETINGS AND REPORTS.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY, LIMITED.

Directors: Alfred Sohier Bolton, Esq.; Sir Frederick J. Bramwell, Bart, F.R S.; G. H. Hopkinson, Esq.; Granville R Ryder, Esq.; R. W. Wallace, Esq.

DIRECTORS' REPORT.

The directors submit to the shareholders a statement of the

Digitized by Google

accounts of the Company, together with a report of the position of the undertaking at the end of the year 1894. The mains, which extended to a length of 16½ miles on December 31, 1893, have been increased during the year 1894 to 18¾ miles. The price of electricity to consumers has been reduced 25 per cent.—viz., from 8d. to 6d. per Board of Trade unit—throughout the district, such reduction having taken effect from July 1 last. During the year the number of houses and shops connected with the system has increased from 734 on December 31, 1893, to 908 on December 31, 1894; while the number of lamps calculated on the usual basis of 8 c.p. has increased from 64,529 to 80,678. The directors have thought it advisable, in view of the increased profits of the Company, to use a large portion of that increase in writing off the balances of the preliminary expenses, and cost of debenture issue account (£500), and of the suspense account (law—£1,199). They also have thought it advisable to strengthen the renewal account by transferring to that account £3,457. 5s. 9d. After providing for the above amounts, and paying the dividends on the 6 per cent. first preference shares to June 30, 1894, on the 5 per cent. second preference shares to September 30, 1894, and an interim dividend at the rate of 5 per cent. per annum on the ordinary shares for the first half of the year, the balance standing to the credit of the net revenue account for the year 1894 is £4,235 14s. 10d. Of the above sum £1,450 has been appropriated to the payment of the first preference dividend to the end of the year, and £150 has to be set aside to meet the portion of the dividend on the second preference shares accrued to the same date, leaving £2,635. 14s. 10d., out of which it is proposed to pay a further dividend on the ordinary shares at the rate of 5 per cent. per annum for the past half-year. This will leave a balance of £823. 4s. 10d. No provision has been made in the accounts for directors' remuneration. In accordance with the articles of association, Sir Frederick J. Bramwell, Bart., F.R.S., and Mr. G. H. Hopkinson retire from the directorship, and, being eligible, offer themselves for re-election. The auditors, Messrs. Lovelock, H. W. S. Whiffin, and Dickinson, offer themselves for re-election.

Mr. A. Sohier Bolton, who presided at the meeting yesterday, moved the adoption of the reports and accounts. In doing so he stated that it was unfortunate that a life had been lost in connection with the Kensington Court station, but that it had nothing to do with electricity. Having referred to the number of lamps connected and the increase in the number of units supplied, the speaker said that this improvement had taken place notwithstanding the fact that the price per unit had been reduced from 8d. to 6d. He put the motion.

Mr. J. H. Hopkinson seconded the motion, which was adopted, and the proceedings terminated.

CHARING CROSS AND STRAND ELECTRICITY SUPPLY CORPORATION, LIMITED.

Directors: G. H. Brougham Glasier, Esq., 7, St. James's-street, S.W. (chairman); Richard Chadwick, Esq., 34, St. Martin's-lane, W.C.; I. P. Mendoza, Esq., 4A, King-street, St. James's, S.W.; Agostino Gatti, Esq., Stefano Gatti, Esq., 436, Strand (managing directors). General manager and secretary: E. Wilmot Seale, Esq. Chief engineer: W. H. Patchell, A.M.I.C.E., M.I.E.E.

DIRECTORS' REPORT.

The directors beg to submit their annual report for 1894, with the accounts for the same period, duly certified by the Company's auditors. The directors have taken steps with a view to obtaining a provisional order for enabling the Company to supply electricity in the district of the Strand Board of Works in accordance with the resolutions arrived at in November last, but no portion of the capital authorised by these resolutions has yet been dealt with. The Corporation was on December 31, 1894, supplying energy to 41,216 8-c.p. lamps, an increase of 19·7 per cent. on the number supplied at the end of the year 1893. There are now upwards of 22 miles of mains laid, and the station has been maintained in all respects in a very high state of efficiency. As will be seen from the accounts, the directors have written £485. 0s. 3d. off preliminary expenses, and carried £1,600 to depreciation account. Provision for bad debts has been made by a deduction of £150 from the amount of sales of current in the manner required by the Board of Trade. The net earnings, as shown in the revenue account, have amounted to £10,395. 12s. 9d.; £3,117. 9s. 2d. has been paid in respect of interest on debentures up to December 31, 1894, and £2,906. 3s. 7d. was distributed in payment of an interim dividend for the half-year ended June 30, 1894. A sum of £3,929. 19s. 10d. now remains, which the directors propose to deal with as follows:

Digitized by Google

Payment of a dividend of 4½ per cent. for the year 1894, less tax	£6,531 3 7	
Interim dividend paid August, 1894	2,906 3 7	
	3,625 0 0	
And to carry forward	304 19 10	
	£3,929 19 10	

Mr. G. H. Brougham Glasier and Mr. I. Percy Mendoza are the directors who retire by rotation, and, being eligible, offer themselves for re-election. The auditors, Messrs. O. R. Johnson and Son, also retire and offer themselves for re election.

In moving the adoption of the report at the meeting yesterday, **Mr. G. H. B. Glasier**, who presided, said that he did not propose to go into figures, but on December 31 last they had 41,216 8-c.p. lamps installed, and 22 miles of mains were laid. Of course this required an outlay of capital, as the mains were laid, not for new lamps, but for probable demand. The past year had been satisfactory, because 2,721 lamps had been added, and the output had increased by 25·21 per cent. as compared with the corresponding period of last year. The directors had written off part of the preliminary expenses, and only £700 had to be dealt with. Last year £700 was placed to the depreciation fund, whereas £1,600 had been put to it this year, which equalled ½ per cent. on the entire share capital. The establishment of a reserve fund was wise, and provision had been made for bad debts. Last year the net earnings were £8,645, and this year £10,395, and this though the average price per unit was ¼d. a unit less than last year.

Digitized by Google

The balance carried over last year was £43, and this year it was £304. The Chairman explained that they had worked their system economically as compared with other London companies, and they would do their best to carry out further economies. In their original prospectus they had said that 10 per cent. dividend could be paid on the shares, and that this might be increased. That statement was made on the authority of their auditor when the price per unit averaged 7¼d. The difference now amounted to £10,028. This equalled on the old basis a dividend of 11¼. The cause of the reduction in price per unit was due to competition. The action of the directors was justified by the Company being in a good position. They were taking steps to obtain a provisional order for a new district, and they would not issue the authorised debentures until this had been obtained.

Mr. Robertson seconded the motion and said that the management had been ably conducted. The price of coal seemed very high, and the Kensington Company obtained more per unit. He thought that their shares should stand higher on the Stock Exchange.

Mr. G. H. B. Glasier and Mr. I. P. Mendoza were re-elected directors, and Messrs. O. R. Johnson and Son as auditors.

WESTMINSTER ELECTRIC SUPPLY CORPORATION, LIMITED.

Directors: The Right Hon. Lord Suffield, K.C.B.; Edmund Boulnois, Esq., M.P.; W. Hayes Fisher, Esq., M.P.; Sir Douglas Galton, K.C.B., F.R.S.; J. Browne Martin, Esq.; James Heslop Powell, Esq.; R. W. Wallace, Esq. General manager: Captain Edmund I. Bax. Engineer-in-Chief: Prof. Alex. B. W. Kennedy, LL.D., F.R.S., M.I.C.E. Secretary: Frank Iago, Esq.

Directors' Report.

The Board of Directors, in presenting their report and the accounts for the year 1894, are pleased to state that the business of the Corporation continues to make satisfactory progress. The supply of current, which on December 31, 1893, was provided for the equivalent of 131,565 lamps of 8 c p, had increased by December 31, 1894, to the equivalent of 167,703, and at the present time there are on circuit the equivalent of 175,695 lamps of 8 c p, and applications have been received for a further 8,817. The length of roadway in which mains have been laid now exceeds 37 miles, making about 148 miles of ways, into which upwards of 115 miles of copper (strip and cable) have been drawn. The plant and machinery have been working satisfactorily throughout the year, and have been fully maintained from revenue. Your Board are also glad to be able to report that a still further reduction has been effected during the past year in the cost per unit, in generating, distributing, and general expenses. Owing to the continued increase in the business of the Corporation, it has been found necessary to provide further capital. In accordance with resolutions passed at extraordinary general meetings, held in October and November last, the share capital was increased from £300,000 to £400,000 by the creation of 20,000 new shares of £5 each, and of this amount £40,000 in 8,000 shares of £5 each has been issued to shareholders in accordance with the resolutions passed at subsequent extraordinary general meetings. In dealing with the revenue of the past year your directors have, after writing off bad debts, proportion of preliminary expenses, the whole of the patent and law charges account, and placing £2,500 to credit of depreciation, added a sum of £2,500 to the sinking fund. The net revenue of the year amounts to £16,168. 18s., out of which an interim dividend at the rate of 4 per cent. per annum for the half year ending June 30, 1894, has been distributed. The Board now recommend the payment of a dividend at the rate of 6 per cent. per annum, less income tax, for the past half-year, making 5 per cent. for the year ending December 31 last, carrying forward a balance of £1,781. In accordance with the articles of association, two of the directors, Edmund Boulnois, Esq., M.P., and Sir Douglas Galton, K.C.B., F.R.S., retire, but, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Bros. and Co., also retire, but, being eligible, offer themselves for re-election.

Total quantity accounted for		2,527,966
Quantity unaccounted for		54,895
Number of lamps on circuit, December 31, 1894		167,703

The annual general meeting of this Company was held on Wednesday at the offices, Eccleston-place, Mr. J. H. Powell occupying the chair in the absence, through illness, of the chairman of the Company, Lord Suffield.

The **Chairman**, in moving the adoption of the report and accounts, said that when the Corporation was first started the principal aim of the directors was to give a constant, safe, and bright light without danger. In carrying out their system they had the advice of an able consulting electrical engineer and architect. They had been so successful in five years that their gross revenue was now £52,692, and this had been obtained not by any sudden turn of tide. The increase last year was greater than before, the advance amounting to £9,000, whereas two years ago it was less than £7,000. A diagram on the wall showed a constant increase in the demand for light, and a correspondingly slighter, but equally constant, increase in the number of lamps installed, which showed that the public had an increased appreciation of their efforts. He had been told by a friend that the question had to be solved of making the undertaking pay, and they had done this by paying a dividend for the half-year at the rate of 6 per cent. The ratio of expenses to income, which had been 59·4 per cent., had now come down to 45·5 per cent., notwithstanding the fact that the price for current had been reduced from 8d. to 6d. This reduction had been a wise stroke of policy, as it had induced fresh customers to come, and made waverers into good friends. In 1892 the expenditure per lamp was £3·56, whereas it was now £2·45, and the directors believed this would be further reduced, owing to their having had to lay down mains in the past in excess of the demand. But it was necessary to do this so as to be able to take on any number of lamps which might be asked for. No metropolitan company spent so little per lamp, and the expenditure in this way would compare favourably with that of any company in the country. Not only had the ratio of expenses decreased, but the actual cost of distribution had decreased. The revenue had advanced by £9,000, and the actual amount of expenses by £500. This reduction was mainly due to the skill and care of the engineers and workmen. They had instituted a system of bonus which seemed to have acted well not only as regarded the engineers and men, but also as regarded the shareholders and consumers. The net revenue amounted to more than 6¼ on the whole of the shares, but deductions had been made. They had done away with the item of cost of patents (which was not an asset); preliminary expenses to the extent of £2,000 had been written off; and £2,500 had been carried to a sinking fund, as the Company's concession was only for 42 years. The directors thought they should provide for the future, as at the end of the period they would not be paid compensation for their business, but only for the plant at a worn-out price. This real reserve fund at the rate of £2,500 a year would, at compound interest, leave a substantial sum for the shareholders at the end of the concession. Prof. Kennedy had also pointed out to them that in the possible event of a new system being invented within, say, 20 years, the Company could utilise this reserve fund for new discoveries, and thus really stand as a new company. Besides, the reserve strengthened the Company at all points.

Mr. E. Boulnois, M.P., seconded the motion, which was adopted.

Mr. Powell proposed, and **Mr. Hayes Fisher** seconded, the distribution of a dividend at the rate of 6 per cent. per annum for the half-year, which was agreed to.

Mr. E. Boulnois, M.P., and Sir Douglas Galton were re-elected directors.

On the motion of **Sir Mark Stewart**, it was agreed to let the matter of the appointment of the Company's auditors stand over until an adjourned meeting.

Mr. S. R. Scott moved, and **Mr. G. White** seconded, that the directors' fees be raised from £800 to £1,500 a year, the increase to date from the beginning of last year. This was unanimously approved of.

NEWCASTLE-UPON-TYNE ELECTRIC SUPPLY COMPANY, LIMITED.

Directors: Alderman T. G. Gibson, J.P. (chairman), Dr. Robt. Spence Watson, Dr. J. T. Merz, Colonel F. F. Sheppee, J. Tennant, Esq., J. H. Armstrong, Esq.

Report of the directors presented to the seventh general meeting of the shareholders.

The amount of share capital subscribed stands at £38,905, of which £34,250 has been paid. This is an increase of £5,735 for the year. The directors were able during the year to arrange for the renewal of the expiring 6 per cent. mortgage debenture issue, amounting to £15,000, at the reduced rate of 5 per cent. A further issue ranking *pari passu* therewith has also been made to the extent of £5,000, of which sum £2,200 was received during the latter part of 1893, in anticipation of the new issue. The total amount of mortgage debentures now represents a sum of £20,000, repayable on September 1, 1899, and bearing interest at 5 per cent. per annum. The expenditure on buildings and plant during the year has been increased by the further cost of completing the condensing plant and extensions of mains. The directors have pleasure in reporting that the condensing plant is now in full operation, and the saving already effected in fuel and water, in their opinion, quite justifies the amount expended. The profit and loss account shows a gross profit of £2,930. 13s. 2d., against £2,459. 16s. 3d. in 1893; the units sold have been 401,066, against 360,467. The net profit for the year is £1,632. 10s., against £1,417. 4s. 11d. in 1895, the charge for interest, owing to increased loan capital, having been £1,298. 3s. 2d., against £1,042. 11s. 4d. in 1893. The directors have transferred the sum of £500 to the reserve fund account, and recommend the payment of a dividend at the rate of 4 per cent per annum, less income tax, of which an interim dividend for the half-year at the same rate was paid on July 18 last. This will absorb in all £1,645. 1s. 9d., leaving a surplus of £288. 4s. to be carried forward to the next year's account. In order to meet the views of the Board of Trade, whose auditor has made a detailed examination of the Company's accounts up to December 31, 1893, an account has been opened, styled "capital expenditure suspense account," to which have been transferred all items of preliminary and formation expenses and extraordinary expenditure necessary to the development of the Company. The transfers to this account represent in total £3,004. 3s. 7d., against which a sum of £1,000 has been transferred from the reserve fund, and it is intended to extinguish the balance of £2,004. 3s. 7d. from time to time out of future profits. The retiring directors are Dr. J. T. Merz and Colonel F. F. Sheppee, who are eligible, and offer themselves for re-election. The auditor, Mr. Thos. Harrison, also retires.

BALANCE-SHEET, DEC. 31, 1894.

Capital and Liabilities.	£	s.	d.
Nominal capital—10,000 shares of £5 each	50,000	0	0
